1 General

1.1 Introduction

vasm is a portable and retargetable assembler able to create linkable objects in different formats as well as absolute code. Different CPU-, syntax and output-modules are supported. Many common directives/pseudo-opcodes are supported (depending on the syntax module) as well as CPU-specific extensions.

The assembler supports optimizations and relaxations (e.g. choosing the shortest possible branch instruction or addressing mode as well as converting a branch to an absolute jump if necessary).

The concept is that you get a special vasm binary for any combination of CPU- and syntax-module. All output modules, which make sense for the current CPU, are included in the vasm binary and you have to make sure to choose the output file format you need (refer to the next chapter and look for the `-F` option). The default is a test output, only useful for debugging or analyzing the output.

1.2 Legal

vasm is copyright in 2002-2014 by Volker Barthelmann.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

1.3 Installation

The vasm binaries do not need additional files, so no further installation is necessary. To use vasm with vbcc, copy the binary to `'vbcc/bin'` after following the installation instructions for vbcc.

The vasm binaries are named `vasm<cpu>_<syntax>` with `<cpu>` representing the CPU-module and `<syntax>` the syntax-module, e.g. vasm for PPC with the standard syntax module is called `vasmppc_std`.

Sometimes the syntax-modifier may be omitted, e.g. `vasmppc`.

Detailed instructions how to build vasm can be found in the last chapter.

2 The Assembler

This chapter describes the module-independent part of the assembler. It documents the options and extensions which are not specific to a certain target, syntax or output driver. Be sure to also read the chapters on the backend, syntax- and output-module you are using. They will likely contain important additional information like data-representation or additional options.

2.1 General Assembler Options

`vasm` is run using the following syntax:

```
vasm<target>_<syntax> [options] file
```

The following options are supported by the machine independent part of `vasm`:

- ‘-D<name>[=expression]’
Defines a symbol with the name <name> and assigns the value of the expression when given. The assigned value defaults to 1 otherwise.
- ‘-esc’
Enable escape character sequences. This will make `vasm` treat the escape character `\` in string constants similar as in the C language.
- ‘-F<fmt>’
Use module <fmt> as output driver. See the chapter on output drivers for available formats and options.
- ‘-I<path>’
Define another include path. They are searched in the order of occurrence on the command line.
- ‘-ignore-mult-inc’
When the same file is included multiple times with the same path this is silently ignored, causing the file to be processed only once. Note that you can still include the same file twice when using different paths to access it.
- ‘-L <listfile>’
Enables generation of a listing file and directs the output into the file <listfile>.
- ‘-Ll<lines>’
Set the number of lines per listing file page to <lines>.
- ‘-Lnf’
Do not emit any form feed code into the listing file, for starting a new page.
- ‘-Lns’
Do not include symbols in the listing file.
- ‘-maxerrors=<n>’
Defines the maximum number of errors to display before assembly is aborted. When <n> is 0 then there is no limit. Defaults to 5.
- ‘-maxmacrecurs=<n>’
Defines the maximum of number of recursions within a macro. Defaults to 1000.
- ‘-nocase’
Disables case-sensitivity for everything - identifiers, directives and instructions. Note that directives and instructions may already be case-insensitive by default in some modules.

- ‘-noesc’ No escape character sequences. This will make vasm treat the escape character \ as any other character. Might be useful for compatibility.
- ‘-nosym’ Strips all local symbols from the output file and doesn’t include any other symbols than those which are required for external linkage.
- ‘-nowarn=<n>’
Disable warning message <n>. <n> has to be the number of a valid warning message, otherwise an error is generated.
- ‘-o <ofile>’
Write the generated assembler output to <ofile> rather than ‘a.out’.
- ‘-pic’ Try to generate position independant code. Every relocation is flagged by an error message.
- ‘-quiet’ Do not print the copyright notice and the final statistics.
- ‘-unnamed-sections’
Sections are no longer distinguished by their name, but only by their attributes. This has the effect that when defining a second section with a different name but same attributes as a first one, it will switch to the first, instead of starting a new section.
- ‘-unsshift’
The shift-right operator (>>) treats the value to shift as unsigned, which has the effect that 0-bits are inserted on the left side. The number of bits in a value depend on the target address type (refer to the appropriate cpu module documentation).
- ‘-w’ Hide all warning messages.
- ‘-x’ Show an error message, when referencing an undefined symbol. The default behaviour is to declare this symbol as externally defined.

Note that while most options allow an argument without any separating blank, some others require it (e.g. ‘-o’ and ‘-L’).

2.2 Expressions

Standard expressions are usually evaluated by the main part of vasm rather than by one of the modules (unless this is necessary).

All expressions evaluated by the frontend are calculated in terms of target address values, i.e. the range depends on the backend.

The available operators include all those which are common in assembler as well as in C expressions.

C like operators:

- Unary: + - ! ~
- Arithmetic: + - * / % << >>
- Bitwise: & | ^
- Logical: && ||

- Comparative: < > <= >= == !=

Assembler like operators:

- Unary: + - ~
- Arithmetic: + - * / // << >>
- Bitwise: & ! ~
- Comparative: < > <= >= = <>

Up to version 1.4b the operators had the same precedence and associativity as in the C language. Newer versions have changed the operator priorities to comply with the common assembler behaviour. The expression evaluation priorities, from highest to lowest, are:

1. + - ! ~ (unary +/- sign, not, complement)
2. << >> (shift left, shift right)
3. & (bitwise and)
4. ^ ~ (bitwise exclusive-or)
5. | ! (bitwise inclusive-or)
6. * / % // (multiply, divide, modulo)
7. + - (plus, minus)
8. < > <= >= (less, greater, less or equal, greater or equal)
9. == != = <> (equality, inequality)
10. && (logical and)
11. || (logical or)

Operands are integral values of the target address type. They can either be specified as integer constants of different bases (see the documentation on the syntax module to see how the base is specified) or character constants. Character constants are introduced by ' or " and have to be terminated by the same character that started them.

Multiple characters are allowed and a constant is built according to the endianness of the target.

When the '-esc' option was specified, or automatically enabled by a syntax module, vasm interprets escape character sequences as in the C language:

\\	Produces a single \.
\b	The bell character.
\f	Form feed.
\n	Line feed.
\r	Carriage return.
\t	Tabulator.
\"	Produces a single ".
\'	Produces a single '.
\e	Escape character (27).

`\<octal-digits>`

One character with the code specified by the digits as octal value.

`\x<hexadecimal-digits>`

One character with the code specified by the digits as hexadecimal value.

`\X<hexadecimal-digits>`

Same as `\x`.

Note, that the default behaviour of vasm has changed since V1.7! Escape sequence handling has been the default in older versions. This has been changed to increase compatibility with other assemblers. Use `-esc` to assemble sources with escape character sequences. It is still the default in the `std` syntax module, though.

2.3 Symbols

You can define as many symbols as your available memory permits. A symbol may have any length and can be of global or local scope. Internally, there are three types of symbols:

Expression

These symbols are usually not visible outside the source, unless they are explicitly exported.

Label

Labels are always addresses inside a program section. By default they have local scope for the linker.

Imported These symbols are externally defined and must be resolved by the linker.

Beginning with vasm V1.5c one expression symbol is always defined to allow conditional assembly depending on the assembler being used: `__VASM`. Its value depends on the selected cpu module. There may be other symbols which are pre-defined by the syntax- or by the cpu module.

2.4 Include Files

Vasm supports include files and defining include paths. Whether this functionality is available depends on the syntax module, which has to provide the appropriate directives.

On startup vasm will define at least one default include path: the current working directory, where the assembler program was launched from. When the input file is loaded from a different directory, i.e. the input file is a relative or absolute path and not a single file name, then the path to the input file name will be added as another include path.

Include paths are searched in the following order:

1. Current work directory.
2. Paths specified by `-I` in the order of occurrence on the command line.
3. Path to the input source file.
4. Paths specified by directives inside the source text (in the order of occurrence).

2.5 Macros

Macros are supported by `vasm`, but the directives for defining them have to be implemented in the syntax module. In any case the assembler core allows up to 9 macro parameters by default (extendable to up to 36 parameters) to be passed in the operand field. They can be referenced inside the macro by `\1` to `\9`. Additionally there is a special argument `\0` which is set to the first qualifier (mnemonic extension) of the macro invocation when given.

A macro parameter which is enclosed inside `<` and `>` characters is treated as a single parameter, even when it contains commas. `>` characters within such a parameter may be specified as `>>`.

`\@` inserts a unique id of the form `_nnnnnn` (where 'n' is a digit between 0 and 9) per macro invocation. Useful for defining reusable labels in a macro.

`\@!` does the same, but pushes the id onto an internal stack.

`\@@` insert the id from top of the id-stack.

`\#` is replaced by the number of parameters given to the current macro invocation.

`\?n` represents the total length of parameter `n` in bytes. Note that the quotes of a string parameter are included in this length.

2.6 Structures

Vasm supports structures, but the directives for defining them have to be implemented in the syntax module.

2.7 Conditional Assembly

Has to be provided completely by the syntax module.

2.8 Known Problems

Some known module-independent problems of `vasm` at the moment:

- None.

2.9 Credits

All those who wrote parts of the `vasm` distribution, made suggestions, answered my questions, tested `vasm`, reported errors or were otherwise involved in the development of `vasm` (in descending alphabetical order, under work, not complete):

- Frank Wille
- Sebastian Pachuta
- Esben Norby
- Gunther Nikl
- George Nakos
- Timm S. Mueller
- Gareth Morris
- Dominic Morris
- Mauricio Muñoz Lucero

- Jörg van de Loo
- Robert Leffmann
- Miro Kropacek
- Mikael Kalms
- Matthew Hey
- Philippe Guichardon
- Romain Giot
- Francois Galea
- Tom Duin
- Karoly Balogh

2.10 Error Messages

The frontend has the following error messages:

- 1: illegal operand types
- 2: unknown mnemonic `<%s>`
- 3: unknown section `<%s>`
- 4: no current section specified
- 5: internal error `%d` in line `%d` of `%s`
- 6: symbol `<%s>` redefined
- 7: `%c` expected
- 8: cannot resolve section `<%s>`, maximum number of passes reached
- 9: instruction not supported on selected architecture
- 10: number or identifier expected
- 11: could not initialize `%s` module
- 12: multiple input files
- 13: could not open `<%s>` for input
- 14: could not open `<%s>` for output
- 15: unknown option `<%s>`
- 16: no input file specified
- 17: could not initialize output module `<%s>`
- 18: out of memory
- 19: symbol `<%s>` recursively defined
- 20: fail: `%s`
- 21: section offset is lower than current pc
- 22: character constant too long
- 23: undefined local symbol
- 24: trailing garbage after option `-%c`
- 25: bad operand
- 26: missing end directive for macro `"%s"`

- 27: macro definition inside macro "%s"
- 28: maximum number of %d macro arguments exceeded
- 29: option -%c was specified twice
- 30: read error on <%s>
- 31: expression must be constant
- 32: initialized data in bss
- 33: missing end directive in repeat-block
- 34: #%d is not a valid warning message
- 35: relocation not allowed
- 36: illegal escape sequence \%c
- 37: no current macro to exit
- 38: internal symbol %s redefined by user
- 39: illegal relocation
- 40: macro id stack overflow
- 41: macro id pull without matching push
- 42: division by zero
- 43: illegal macro argument
- 44: reloc org is already set
- 45: reloc org was not set
- 46: macro id insert on empty stack
- 47: bad file-offset argument
- 48: assertion "%s" failed: %s
- 49: cannot declare structure within structure
- 50: no structure
- 51: instruction has been auto-aligned
- 52: macro name conflicts with mnemonic
- 53: macro name conflicts with directive
- 54: non-relocatable expression in equate <%s>
- 55: line buffer overflow
- 56: illegal structure recursion
- 57: maximum number of macro recursions (%d) reached
- 58: data has been auto-aligned
- 59: register symbol <%s> redefined

3 Standard Syntax Module

This chapter describes the standard syntax module which is available with the extension `std`.

3.1 Legal

This module is copyright in 2002-2014 by Volker Barthelmann.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

3.2 Additional options for this version

This syntax module provides the following additional options:

- ‘`-ac`’ Immediately allocate common symbols in `.bss/.sbss` section and define them as externally visible.
- ‘`-nodotneeded`’ Recognize assembly directives without a leading dot (`.`).
- ‘`-noesc`’ Ignore escape character sequences in string constants.
- ‘`-sdlimit=<n>`’ Put data up to a maximum size of `n` bytes into the small-data sections. Default is `n=0`, which means the function is disabled.

3.3 General Syntax

Labels have to be terminated with a colon (`:`). Local labels are preceded by `'.'` and have to contain digits only. Local labels are valid between two global label definitions.

Make sure that you don't define a label on the same line as a directive for conditional assembly (if, else, endif)! This is not supported.

The operands are separated from the mnemonic by whitespace. Multiple operands are separated by comma (`,`).

Comments are introduced by the comment character `#`. The rest of the line will be ignored. For the `c16x`, `m68k`, `650x` and ARM backends, the comment character is `;` instead of `#`, although `#` is still allowed when being the first non-blank character on a line.

Example:

```
mylabel: inst.q1.q2 op1,op2,op3 # comment
```

In expressions, numbers starting with `0x` or `0X` are hexadecimal (e.g. `0xfb2c`). `0b` or `0B` introduces binary numbers (e.g. `0b1100101`). Other numbers starting with `0` are assumed to be octal numbers, e.g. `0237`. All numbers starting with a non-zero digit are decimal, e.g. `1239`.

C-like escape characters in string constants are allowed by default, unless disabled by ‘`-noesc`’.

3.4 Directives

The following directives are supported by this syntax module (if the CPU- and output-module allow it):

- `.2byte <exp1>[, <exp2>...]`
See `.uahalf`.
- `.4byte <exp1>[, <exp2>...]`
See `.uaword`.
- `.8byte <exp1>[, <exp2>...]`
See `.uaquad`.
- `.ascii <exp1>[, <exp2>, "<string1>"...]`
See `.byte`.
- `.abort <message>`
Print an error and stop assembly immediately.
- `.asciiz "<string1>"[, "<string2>"...]`
See `.string`.
- `.align <bit_count>[, <fill>]`
Insert as much fill bytes as required to reach an address where `<bit_count>` low order bits are zero. For example `.align 2` would make an alignment to the next 32-bit boundary. Note that this directive
- `.balign <byte_count>[, <fill>]`
Insert as much fill bytes as required to reach an address which is dividable by `<byte_count>`. For example `.balign 2` would make an alignment to the next 16-bit boundary.
- `.byte <exp1>[, <exp2>, "<string1>"...]`
Assign the integer or string constant operands into successive bytes of memory in the current section. Any combination of integer and character string constant operands is permitted.
- `.comm <symbol>, <size>[, <align>]`
Defines a common symbol which has a size of `<size>` bytes. The final size and alignment will be assigned by the linker, which will use the highest size and alignment values of all common symbols with the same name found. A common symbol is allocated in the `.bss` section in the final executable. ".comm"-areas of less than 8 bytes in size are aligned to word boundaries, other- wise to doubleword boundaries.
- `.endm` Ends a macro definition.
- `.endr` Ends a repetition block.
- `.equ <symbol>, <expression>`
See `.set`.
- `.err <message>`
Print a user error message. Do not create an output file.

`.extern <symbol>[,<symbol>...]`
See `.global`.

`.fail <expression>`
Cause a warning when `<expresion>` is greater or equal 500. Otherwise cause an error.

`.file "string"`
Set the filename of the input source. This may be used by some output modules. By default, the input filename passed on the command line is used.

`.global <symbol>[,<symbol>...]`
Flag `<symbol>` as an external symbol, which means that `<symbol>` is visible to all modules in the linking process. It may be either defined or undefined.

`.globl <symbol>[,<symbol>...]`
See `.global`.

`.half <exp1>[,<exp2>...]`
If the current section location counter is not on a halfword boundary, advance it to the next halfword boundary. Then, assign the values of the operands into successive halfwords of memory in the current section.

`.if <expression>`
Conditionally assemble the following lines if `<expression>` is non-zero.

`.ifeq <expression>`
Conditionally assemble the following lines if `<expression>` is zero.

`.ifne <expression>`
Conditionally assemble the following lines if `<expression>` is non-zero.

`.ifgt <expression>`
Conditionally assemble the following lines if `<expression>` is greater than zero.

`.ifge <expression>`
Conditionally assemble the following lines if `<expression>` is greater than zero or equal.

`.iflt <expression>`
Conditionally assemble the following lines if `<expression>` is less than zero.

`.ifle <expression>`
Conditionally assemble the following lines if `<expression>` is less than zero or equal.

`.ifb <operand>`
Conditionally assemble the following lines when `<operand>` is completely blank, except an optional comment.

`.ifnb <operand>`
Conditionally assemble the following lines when `<operand>` is non-blank.

`.ifdef <symbol>`
Conditionally assemble the following lines if `<symbol>` is defined.

- .ifndef <symbol>**
Conditionally assemble the following lines if <symbol> is undefined.
- .incbin <file>**
Inserts the binary contents of <file> into the object code at this position. The file will be searched first in the current directory, then in all paths defined by '-I' or **.incdir** in the order of occurrence.
- .incdir <path>**
Add another path to search for include files to the list of known paths. Paths defined with '-I' on the command line are searched first.
- .include <file>**
Include source text of <file> at this position. The include file will be searched first in the current directory, then in all paths defined by '-I' or **.incdir** in the order of occurrence.
- .int <exp1>[,<exp2>...]**
See **.word**.
- .lcomm <symbol>,<size>[,<alignment>]**
Allocate <size> bytes of space in the .bss section and assign the value to that location to <symbol>. If <alignment> is given, then the space will be aligned to an address having <alignment> low zero bits or 2, whichever is greater. <symbol> may be made globally visible by the **.globl** directive.
- .list** The following lines will appear in the listing file, if it was requested.
- .local <symbol>[,<symbol>...]**
Flag <symbol> as a local symbol, which means that <symbol> is local for the current file and invisible to other modules in the linking process.
- .long <exp1>[,<exp2>...]**
See **.word**.
- .macro <name> [<arguments>...]**
Defines a macro which can be referenced by <name>. The macro definition is closed by an **.endm** directive. When calling a macro you may pass up to 9 arguments, separated by comma. Those arguments are referenced within the macro context as \1 to \9, or optionally by named arguments, which may be specified after the <name>, separated by commas. Argument \0 is set to the macro's first qualifier (mnemonic extension), when given. The special argument \@ inserts a unique id, useful for defining labels. \() may be used as a separator between the name of a macro argument and the subsequent text.
- .nolist** The following lines will not be visible in a listing file.
- .org <exp>**
Defines the start address for the subsequent code. When <exp> starts with a current-pc symbol and a plus (+) operator, then the directive behaves like **.space**.

`.quad <exp1>[,<exp2>...]`

If the current section location counter is not on a quadword boundary, advance it to the next quadword boundary. Then, assign the values of the operands into successive quadwords of memory in the current section.

`.rept <expression>`

Repeats the assembly of the block between `.rept` and `.endr` `<expression>` number of times. `<expression>` has to be positive.

`.section <name>[, "<attributes>"]`

Starts a new section named `<name>` or reactivate an old one. If attributes are given for an already existing section, they must match exactly. The section's name will also be defined as a new symbol, which represents the section's start address. The "`<attributes>`" string may consist of the following characters:

Section Contents:

<code>c</code>	section has code
<code>d</code>	section has initialized data
<code>u</code>	section has uninitialized data
<code>i</code>	section has directives (info section)
<code>n</code>	section can be discarded
<code>R</code>	remove section at link time
<code>a</code>	section is allocated in memory

Section Protection:

<code>r</code>	section is readable
<code>w</code>	section is writable
<code>x</code>	section is executable
<code>s</code>	section is sharable

Section Alignment: A digit, which is ignored. The assembler will automatically align the section to the highest alignment restriction used within.

Memory flags (Amiga hunk format only):

<code>C</code>	load section to Chip RAM
<code>F</code>	load section to Fast RAM

`.set <symbol>,<expression>`

Create a new program symbol with the name `<symbol>` and assign to it the value of `<expression>`. If `<symbol>` is already assigned, it will contain a new value from now on.

`.size <symbol>,<size>`

Set the size in bytes of an object defined at `<symbol>`.

`.short <exp1>[,<exp2>...]`

See `.half`.

.space <exp>[,<fill>]
 Insert <exp> zero or <fill> bytes into the current section.

.stabs "<name>",<type>,<other>,<desc>,<exp>
 Add an stab-entry for debugging, including a symbol-string and an expression.

.stabn <type>,<other>,<desc>,<exp>
 Add an stab-entry for debugging, without a symbol-string.

.stabd <type>,<other>,<desc>
 Add an stab-entry for debugging, without symbol-string and value.

.string "<string1>":["<string2>"...]
 Like **.byte**, but adds a terminating zero-byte.

.type <symbol>,<type>
 Set type of symbol called <symbol> to <type>, which must be one of:

- 1: Object
- 2: Function
- 3: Section
- 4: File

The predefined symbols **@object** and **@function** are available for this purpose.

.uahalf <exp1>[,<exp2>...]
 Assign the values of the operands into successive two-byte areas of memory in the current section regardless of section alignment.

.ualong <exp1>[,<exp2>...]
 See **.uaword**.

.uaquad <exp1>[,<exp2>...]
 Assign the values of the operands into successive eight-byte areas of memory in the current section regardless of section alignment.

.uashort <exp1>[,<exp2>...]
 See **.uahalf**.

.uaword <exp1>[,<exp2>...]
 Assign the values of the operands into successive four-byte areas of memory in the current section regardless of section alignment.

.weak <symbol>[,<symbol>...]
 Flag <symbol> as a weak symbol, which means that <symbol> is visible to all modules in the linking process and may be replaced by any global symbol with the same name. When a weak symbol remains undefined its value defaults to 0.

.word <exp1>[,<exp2>...]
 If the current section location counter is not on a word boundary advance it to the next word boundary. Then assign the values of the operands into successive words of memory in the current section.

Predefined section directives:

```
.bss      .section ".bss","aurw"  
.data     .section ".data","adrw"  
.rodata   .section ".rodata","adr"  
.sbss     .section ".sbss","aurw"  
.sdata    .section ".sdata","adrw"  
.sdata2   .section ".sdata2","adr"  
.stab     .section ".stab","dr"  
.stabstr  .section ".stabstr","dr"  
.text     .section ".text","acrx"  
.tocd     .section ".tocd","adrw"
```

3.5 Known Problems

Some known problems of this module at the moment:

- None.

3.6 Error Messages

This module has the following error messages:

- 1001: mnemonic expected
- 1002: invalid extension
- 1003: no space before operands
- 1004: too many closing parentheses
- 1005: missing closing parentheses
- 1006: missing operand
- 1007: scratch at end of line
- 1008: \" expected
- 1009: invalid data operand
- 1010: , expected
- 1011: identifier expected
- 1012: assembly aborted
- 1013: expression must be constant
- 1014: unexpected endm without macro
- 1015: endif without if
- 1016: if without endif
- 1017: maximum if-nesting depth exceeded (%d levels)
- 1018: else without if
- 1019: syntax error
- 1020: unexpected endr without rept
- 1021: symbol <%s> already defined with %s scope

4 Mot Syntax Module

This chapter describes the Motorola syntax module, mostly used for the M68k and ColdFire families of CPUs, which is available with the extension `mot`.

4.1 Legal

This module is copyright in 2002-2014 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

4.2 Additional options for this version

This syntax module provides the following additional options:

- ‘`-align`’ Enables natural alignment for constant declaration (`dc.?`) directives.
- ‘`-devpac`’ Devpac-compatibility mode.
 - Enables natural alignment for constant declaration (`dc.?`) directives.
 - Predefines offset symbols `__RS`, `__S0` and `__F0` as 0, which in vasm are undefined until first referenced.
 - Disable escape codes handling in strings (see ‘`-noesc`’).
 - Enable dots within identifiers (see ‘`-ldots`’).
 - Up to 35 macro arguments.
- ‘`-ldots`’ Allow dots (`.`) within all identifiers.
- ‘`-localu`’ Local symbols are prefixed by ‘`_`’ instead of ‘`.`’. For Devpac compatibility, which offers a similar option.
- ‘`-phxass`’ PhxAss-compatibilty mode. Enables the following features:
 - `section <name>` starts a code section named `<name>` instead of a section which also has the type `<name>`.
 - Enable escape codes handling in strings (see ‘`-esc`’).
 - Macro names are treated as case-insensitive.
 - Up to 35 macro arguments.
 - Allow blanks in operands.
 - Defines the symbol `_PHXASS_` with value 2 (to differentiate from the real PhxAss with value 1).
 - When no output file name is given, construct it from the input name.
- ‘`-spaces`’ Allow blanks in operands.

4.3 General Syntax

Labels must either start at the first column of a line or need to be terminated by a colon (:). In the first case the mnemonic has to be separated from the label by whitespace (not required in any case, e.g. with a = directive). Qualifiers are appended to the mnemonic, separated by a dot (if the CPU-module supports qualifiers). The operands are separated from the mnemonic by whitespace. Multiple operands are separated by comma (,).

Local labels are preceded by '.' or terminated by '\$'. For the rest, any alphanumeric character including '_' is allowed. Local labels are valid between two global label definitions.

Otherwise dots (.) are not allowed within a label by default, unless the option '-ldots' or '-devpac' was specified. Even then, labels ending on .b, .w or .l can't be defined.

It is possible to refer to any local symbol in the source by preceding its name with the name of the last global symbol, which was defined before: `global_name\local_name`. This is for PhxAss compatibility only, and is no recommended style. Does not work in a macro, as it conflicts with macro arguments.

Make sure that you don't define a label on the same line as a directive for conditional assembly (if, else, endif)! This is not supported.

In this syntax module, the operand field must not contain any whitespace characters, as long as the option '-spaces' was not specified.

Comments are introduced by the comment character ; or *. The rest of the line will be ignored. Also everything following the operand field, separated by a whitespace, will be regarded as comment (unless '-spaces'). Be careful with *, which is recognized as the "current pc symbol" in any operand expression

Example:

```
mylabel inst.q op1,op2,op3 ;comment
```

In expressions, numbers starting with \$ are hexadecimal (e.g. \$fb2c). % introduces binary numbers (e.g. %1100101). Numbers starting with @ are assumed to be octal numbers, e.g. @237. All numbers starting with a digit are decimal, e.g. 1239.

4.4 Directives

The following directives are supported by this syntax module (provided the CPU- and output-module support them):

```
<symbol> = <expression>
```

Equivalent to <symbol> equ <expression>.

```
<symbol> =.s <expression>
```

Equivalent to <symbol> fequ.s <expression>. PhxAss compatibility.

```
<symbol> =.d <expression>
```

Equivalent to <symbol> fequ.d <expression>. PhxAss compatibility.

```
<symbol> =.x <expression>
```

Equivalent to <symbol> fequ.x <expression>. PhxAss compatibility.

```
<symbol> =.p <expression>
```

Equivalent to <symbol> fequ.p <expression>. PhxAss compatibility.

align <bitcount>	Insert as much zero bytes as required to reach an address where <bitcount> low order bits are zero. For example align 2 would make an alignment to the next 32-bit boundary. Equivalent to cnop 0,1<bitcount> .
blk.b <exp>[,<fill>]	Equivalent to dcbl.b <exp>,<fill> .
blk.d <exp>[,<fill>]	Equivalent to dcbl.d <exp>,<fill> .
blk.l <exp>[,<fill>]	Equivalent to dcbl.l <exp>,<fill> .
blk.q <exp>[,<fill>]	Equivalent to dcbl.q <exp>,<fill> .
blk.s <exp>[,<fill>]	Equivalent to dcbl.s <exp>,<fill> .
blk.w <exp>[,<fill>]	Equivalent to dcbl.w <exp>,<fill> .
blk.x <exp>[,<fill>]	Equivalent to dcbl.x <exp>,<fill> .
bss	Equivalent to section bss , bss .
bss_c	Equivalent to section bss_c , bss , chip .
bss_f	Equivalent to section bss_f , bss , fast .
cargs [#<offset>,<symbol1>[.<size1>][,<symbol2>[.<size2>]]...	Defines <symbol1> with the value of <offset>. Further symbols on the line, separated by comma, will be assigned the <offset> plus the size of the previous symbol. The size defaults to 2. Valid optional size extensions are: .b , .w , .l , where .l results in a size of 4, the others 2. The <offset> argument defaults to 4, when not given.
clrfo	Reset stack-frame offset counter to zero. See fo directive.
clrso	Reset structure offset counter to zero. See so directive.
cnop <offset>,<alignment>	Insert as much zero bytes as required to reach an address which can be divided by <alignment>. Then add <offset> zero bytes.
code	Equivalent to section code , code .
code_c	Equivalent to section code_c , code , chip .
code_f	Equivalent to section code_f , code , fast .
comment	Everything in the operand field is ignored and seen as a comment. There is only one exception, when the operand contains HEAD= . Then the following expression is passed to the TOS output module via the symbol 'TOSFLAGS', to define the Atari specific TOS flags.

cseg Equivalent to `section code,code`.

data Equivalent to `section data,data`.

data_c Equivalent to `section data_c,data,chip`.

data_f Equivalent to `section data_f,data,fast`.

dc.b <exp1>[,<exp2>,"<string1>",<string2>'...]
 Assign the integer or string constant operands into successive bytes of memory in the current section. Any combination of integer and character string constant operands is permitted.

dc.d <exp1>[,<exp2>...]
 Assign the values of the operands into successive 64-bit words of memory in the current section. Also IEEE double precision floating point constants are allowed.

dc.l <exp1>[,<exp2>...]
 Assign the values of the operands into successive 32-bit words of memory in the current section.

dc.q <exp1>[,<exp2>...]
 Assign the values of the operands into successive 64-bit words of memory in the current section.

dc.s <exp1>[,<exp2>...]
 Assign the values of the operands into successive 32-bit words of memory in the current section. Also IEEE single precision floating point constants are allowed.

dc.w <exp1>[,<exp2>...]
 Assign the values of the operands into successive 16-bit words of memory in the current section.

dc.x <exp1>[,<exp2>...]
 Assign the values of the operands into successive 96-bit words of memory in the current section. Also IEEE extended precision floating point constants are allowed.

dcb.b <exp>[,<fill>]
 Insert <exp> zero or <fill> bytes into the current section.

dcb.d <exp>[,<fill>]
 Insert <exp> zero or <fill> 64-bit words into the current section. <fill> might also be an IEEE double precision constant.

dcb.l <exp>[,<fill>]
 Insert <exp> zero or <fill> 32-bit words into the current section.

dcb.q <exp>[,<fill>]
 Insert <exp> zero or <fill> 64-bit words into the current section.

dcb.s <exp>[,<fill>]
 Insert <exp> zero or <fill> 32-bit words into the current section. <fill> might also be an IEEE single precision constant.

`dcb.w <exp>[,<fill>]`
 Insert <exp> zero or <fill> 16-bit words into the current section.

`dcb.x <exp>[,<fill>]`
 Insert <exp> zero or <fill> 96-bit words into the current section. <fill> might also be an IEEE extended precision constant.

`dr.b <exp1>[,<exp2>...]`
 Calculates <expN> - <current pc value> and stores it into successive bytes of memory in the current section.

`dr.w <exp1>[,<exp2>...]`
 Calculates <expN> - <current pc value> and stores it into successive 16-bit words of memory in the current section.

`dr.l <exp1>[,<exp2>...]`
 Calculates <expN> - <current pc value> and stores it into successive 32-bit words of memory in the current section.

`ds.b <exp>`
 Equivalent to `dcb.b <exp>,0`.

`ds.d <exp>`
 Equivalent to `dcb.d <exp>,0`.

`ds.l <exp>`
 Equivalent to `dcb.l <exp>,0`.

`ds.q <exp>`
 Equivalent to `dcb.q <exp>,0`.

`ds.s <exp>`
 Equivalent to `dcb.s <exp>,0`.

`ds.w <exp>`
 Equivalent to `dcb.w <exp>,0`.

`ds.x <exp>`
 Equivalent to `dcb.x <exp>,0`.

`dseg` Equivalent to `section data,data`.

`echo <string>`
 Prints <string> to stdout.

`else` Assemble the following lines if the previous `if` condition was false.

`end` Assembly will terminate behind this line.

`endif` Ends a section of conditional assembly.

`endm` Ends a macro definition.

`endr` Ends a repetition block.

`<symbol> equ <expression>`
 Define a new program symbol with the name <symbol> and assign to it the value of <expression>. Defining <symbol> twice will cause an error.

`<symbol> equ.s <expression>`
 Equivalent to `<symbol> frequ.s <expression>`. PhxAss compatibility.

`<symbol> equ.d <expression>`
 Equivalent to `<symbol> frequ.d <expression>`. PhxAss compatibility.

`<symbol> equ.x <expression>`
 Equivalent to `<symbol> frequ.x <expression>`. PhxAss compatibility.

`<symbol> equ.p <expression>`
 Equivalent to `<symbol> frequ.p <expression>`. PhxAss compatibility.

`erem` Ends an outcommented block. Assembly will continue.

`even` Aligns to an even address. Equivalent to `cnop 0,2`.

`fail <message>`
 Show an error message including the `<message>` string. Do not generate an output file.

`<symbol> frequ.s <expression>`
 Define a new program symbol with the name `<symbol>` and assign to it the floating point value of `<expression>`. Defining `<symbol>` twice will cause an error. The extension is for Devpac-compatibility, but will be ignored.

`<symbol> frequ.d <expression>`
 Equivalent to `<symbol> frequ.s <expression>`.

`<symbol> frequ.x <expression>`
 Equivalent to `<symbol> frequ.s <expression>`.

`<symbol> frequ.p <expression>`
 Equivalent to `<symbol> frequ.s <expression>`.

`<label> fo.<size> <expression>`
 Assigns the current value of the stack-frame offset counter to `<label>`. Afterwards the counter is decremented by the instruction's `<size>` multiplied by `<expression>`. Any valid M68k size extension is allowed for `<size>`: b, w, l, q, s, d, x, p. The offset counter can also be referenced directly under the name `__F0`.

`idnt <name>`
 Sets the file or module name in the generated object file to `<name>`, when the selected output module supports it. By default, the input filename passed on the command line is used.

`if <expression>`
 Conditionally assemble the following lines if `<expression>` is non-zero.

`ifeq <expression>`
 Conditionally assemble the following lines if `<expression>` is zero.

`ifne <expression>`
 Conditionally assemble the following lines if `<expression>` is non-zero.

`ifgt <expression>`
 Conditionally assemble the following lines if `<expression>` is greater than zero.

ifge <expression>
Conditionally assemble the following lines if <expression> is greater than zero or equal.

iflt <expression>
Conditionally assemble the following lines if <expression> is less than zero.

ifle <expression>
Conditionally assemble the following lines if <expression> is less than zero or equal.

ifb <operand>
Conditionally assemble the following lines when <operand> is completely blank, except an optional comment.

ifnb <operand>
Conditionally assemble the following lines when <operand> is non-blank.

ifc <string1>,<string2>
Conditionally assemble the following lines if <string1> matches <string2>.

ifnc <string1>,<string2>
Conditionally assemble the following lines if <string1> does not match <string2>.

ifd <symbol>
Conditionally assemble the following lines if <symbol> is defined.

ifnd <symbol>
Conditionally assemble the following lines if <symbol> is undefined.

incbin <file>
Inserts the binary contents of <file> into the object code at this position. The file will be searched first in the current directory, then in all paths defined by '-I' or **incdir** in the order of occurrence.

incdir <path>
Add another path to search for include files to the list of known paths. Paths defined with '-I' on the command line are searched first.

include <file>
Include source text of <file> at this position. The include file will be searched first in the current directory, then in all paths defined by '-I' or **incdir** in the order of occurrence.

list
The following lines will appear in the listing file, if it was requested.

llen <len>
Set the line length in a listing file to a maximum of <len> characters. Currently without any effect.

macro <name>
Defines a macro which can be referenced by <name>. The <name> may also appear at the left side of the **macro** directive, starting at the first column. Then the operand field is ignored. The macro definition is closed by an **endm** directive. When calling a macro you may pass up to 9 arguments, separated

by comma. Those arguments are referenced within the macro context as \1 to \9. Argument \0 is set to the macro's first qualifier (mnemonic extension), when given. In Devpac- and PhxAss-compatibility mode up to 35 arguments are accepted, where argument 10-35 can be referenced by \a to \z. The special argument \@ inserts a unique id, useful for defining labels. \# is replaced by the number of arguments (also stored in NARG) and \?n is replaced by the length of argument n. \. selects the argument indexed by the current value of CARG. \+ and \- do the same, but additionally post-increment and post-decrement CARG. \() may be used as a separator between the name of a macro argument and the subsequent text.

mexit Leave the current macro and continue with assembling the parent context. Note that this directive also resets the level of conditional assembly to a state before the macro was invoked (which means that it works as a 'break' command on all new **if** directives).

nolist The following lines will not be visible in a listing file.

nopage Never start a new page in the listing file. This implementation will only prevent emitting the formfeed code.

odd Aligns to an odd address. Equivalent to **cnop 1,2**.

offset [<expression>]

Switches to a special offset-section. The contents of such a section is not included in the output. Their labels may be referenced as absolute offset symbols. Can be used to define structure offsets. The optional <expression> gives the start offset for this section. When missing the last offset of the previous offset-section is used, or 0.

org <expression>

Sets the base address for the subsequent code.

output <name>

Sets the output file name to <name> when no output name was given on the command line. A special case for Devpac-compatibility is when <name> starts with a '.' and an output name was already given. Then the current output name gets <name> appended as an extension. When an extension already exists, then it is replaced.

page Start a new page in the listing file (not implemented). Make sure to start a new page when the maximum page length is reached.

plen <len>

The the page length for a listing file to <len> lines. Currently ignored.

printt <string>

Prints <string> to stdout.

printv <expression>

Evaluate <expression> and print it to stdout out in decimal and hexadecimal form.

public <symbol>[,<symbol>...]
 Flag <symbol> as an external symbol, which means that <symbol> is visible to all modules in the linking process. It may be either defined or undefined.

rem
 The assembler will ignore everything from encountering the **rem** directive until an **erem** directive was found.

rept <expression>
 Repeats the assembly of the block between **rept** and **endr** <expression> number of times. <expression> has to be positive. The internal symbol **REPTN** always holds the iteration counter of the inner repeat loop, starting with 0. **REPTN** is -1 outside of any repeat block.

rorg <expression>
 Sets the program counter <expression> bytes behind the start of the current section. The new program counter must not be smaller than the current one. The space will be padded with zeros.

<label> **rs.<size>** <expression>
 Works like the **so** directive, with the only difference that the offset symbol is named **__RS**.

rsreset
 Equivalent to **clrso**, but the symbol manipulated is **__RS**.

rsset
 Equivalent to **setso**, but the symbol manipulated is **__RS**.

section [<name>,<sec_type>[,<mem_type>]]
 Starts a new section named <name> or reactivates an old one. <sec_type> defines the section type and may be **code**, **text** (same as **code**), **data** or **bss**. <sec_type> defaults to **code** in Phxass mode. Otherwise a single argument will start a section with the type and name of <sec_type>. When <mem_type> is given it defines the type of memory, where the section can be loaded. This is Amiga-specific, and allowed identifiers are **chip** for Chip-RAM and **fast** for Fast-RAM. Optionally it is also possible to attach the suffix **_C**, **_F** or **_P** to the <sec_type> argument for defining the memory type.

<symbol> **set** <expression>
 Create a new symbol with the name <symbol> and assign the value of <expression>. If <symbol> is already assigned, it will contain a new value from now on.

setfo <expression>
 Sets the stack-frame offset counter to <expression>. See **fo** directive.

setso <expression>
 Sets the structure offset counter to <expression>. See **so** directive.

<label> **so.<size>** <expression>
 Assigns the current value of the structure offset counter to <label>. Afterwards the counter is incremented by the instruction's <size> multiplied by <expression>. Any valid M68k size extension is allowed for <size>: **b**, **w**, **l**, **q**, **s**, **d**, **x**, **p**. The offset counter can also be referenced directly under the name **__S0**.

spc <lines>
 Output <lines> number of blank lines in the listing file. Currently without any effect.

text Equivalent to **section code,code**.

ttl <name>
 PhxAss syntax. Equivalent to **idnt** <name>.

<name> **ttl**
 Motorola syntax. Equivalent to **idnt** <name>.

xdef <symbol>[,<symbol>...]
 Flag <symbol> as an global symbol, which means that <symbol> is visible to all modules in the linking process. See also **public**.

xref <symbol>[,<symbol>...]
 Flag <symbol> as externally defined, which means it has to be important from another module in the linking process. See also **public**.

4.5 Known Problems

Some known problems of this module at the moment:

- None?

4.6 Error Messages

This module has the following error messages:

- 1001: mnemonic expected
- 1002: invalid extension
- 1003: no space before operands
- 1004: too many closing parentheses
- 1005: missing closing parentheses
- 1006: missing operand
- 1007: garbage at end of line
- 1008: syntax error
- 1009: invalid data operand
- 1010: , expected
- 1011: identifier expected
- 1012: directive has no effect
- 1013: expression must be a constant
- 1014: illegal section type
- 1015: repeatedly defined symbol
- 1016: illegal memory type
- 1017: unexpected %s without %s
- 1018: endc/endif missing for conditional block started at %s line %d
- 1020: maximum if-nesting depth exceeded (%d levels)
- 1022: missing %c

5 Oldstyle Syntax Module

This chapter describes the oldstyle syntax module suitable for some 8-bit CPUs (6502, 680x, 68HC1x, Z80, etc.), which is available with the extension `oldstyle`.

5.1 Legal

This module is copyright in 2002-2014 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

5.2 Additional options for this version

This syntax module provides the following additional options:

`‘-dotdir’` Directives have to be preceded by a dot (.).

`‘-autoexp’`
Automatically export all non-local symbols, making them visible to other modules during linking.

5.3 General Syntax

Labels always start at the first column and may be terminated by a colon (:), but don't need to. In the last case the mnemonic needs to be separated from the label by whitespace (not required in any case, e.g. =).

Local labels are preceded by `‘.’` or terminated by `‘$’`. For the rest, any alphanumeric character including `‘_’` is allowed. Local labels are valid between two global label definitions. It is allowed, but not recommended, to refer to any local symbol starting with `‘.’` in the source, by preceding its name with the name of the last global symbol, which was defined before it: `global_name.local_name`.

The operands are separated from the mnemonic by whitespace. Multiple operands are separated by comma (,).

Make sure that you don't define a label on the same line as a directive for conditional assembly (if, else, endif)! This is not supported.

Comments are introduced by the comment character `‘;’`. The rest of the line will be ignored.

Example:

```
mylabel instr op1,op2 ;comment
```

In expressions, numbers starting with `$` are hexadecimal (e.g. `$fb2c`). For Z80 also `&` may be used as a hexadecimal prefix, but make sure to avoid conflicts with the and-operator (either by using parentheses or blanks). `%` introduces binary numbers (e.g. `%1100101`). Numbers starting with `@` are assumed to be octal numbers, e.g. `@237` (except for Z80, where it means binary). A special case is a digit followed by a `#`, which can be used to define an arbitrary base between 2 and 9 (e.g. `4#3012`). Intel-style constant suffixes are supported: `h` for hexadecimal, `d` for decimal, `o` or `q` for octal and `b` for binary. Hexadecimal intel-style

constants must start with a digit (prepend 0, when required). Also C-style prefixes are supported for hexadecimal (0x) and binary (0b). All other numbers starting with a digit are decimal, e.g. 1239.

5.4 Directives

The following directives are supported by this syntax module (if the CPU- and output-module allow it):

<symbol> = <expression>

Equivalent to **<symbol> equ <expression>**.

abyte <offset>[,<exp1>[,<exp2>,"<string1>"...]

Write the integer or string constant operands into successive bytes of memory in the current section while adding the constant <offset> to each byte. Any combination of integer and character string constant operands is permitted.

addr <exp1>[,<exp2>...]

Equivalent to **word <exp1>[,<exp2>...]**.

align <bitcount>

Insert as much zero bytes as required to reach an address where <bit_count> low order bits are zero. For example **align 2** would make an alignment to the next 32-bit boundary.

asc <exp1>[,<exp2>,"<string1>"...]

Equivalent to **byte <exp1>[,<exp2>,"<string1>"...]**.

ascii <exp1>[,<exp2>,"<string1>"...]

See **defm**.

asciiz "<string1>"[, "<string2>"...]

See **string**.

assert <expression>[,<message>]

Display an error with the optional <message> when the expression is false.

binary <file>

Inserts the binary contents of <file> into the object code at this position. The file will be searched first in the current directory, then in all paths defined by '-I' or **incdir** in the order of occurrence.

blk <exp>[,<fill>]

Insert <exp> zero or <fill> bytes into the current section.

blkw <exp>[,<fill>]

Insert <exp> zero or <fill> 16-bit words into the current section, using the endianness of the target CPU.

bsz exp[,<fill>]

Equivalent to **blk <exp>[,<fill>]**.

byt

Increases the program counter by one. Equivalent to **blk 1,0**.

`byte <exp1>[,<exp2>,<"string1">...]`
Assign the integer or string constant operands into successive bytes of memory in the current section. Any combination of integer and character string constant operands is permitted.

`data <exp1>[,<exp2>,<"string1">...]`
Equivalent to `byte <exp1>[,<exp2>,<"string1">...]`.

`db <exp1>[,<exp2>,<"string1">...]`
Equivalent to `byte <exp1>[,<exp2>,<"string1">...]`.

`dc <exp>[,<fill>]`
Equivalent to `blk <exp>[,<fill>]`.

`defb <exp1>[,<exp2>,<"string1">...]`
Equivalent to `byte <exp1>[,<exp2>,<"string1">...]`.

`defc <symbol> = <expression>`
Define a new program symbol with the name <symbol> and assign to it the value of <expression>. Defining <symbol> twice will cause an error.

`defl <exp1>[,<exp2>...]`
Assign the values of the operands into successive 32-bit integers of memory in the current section, using the endianness of the target CPU.

`defp <exp1>[,<exp2>...]`
Assign the values of the operands into successive 24-bit integers of memory in the current section, using the endianness of the target CPU.

`defm "string"`
Equivalent to `text "string"`.

`defw <exp1>[,<exp2>...]`
Equivalent to `word <exp1>[,<exp2>...]`.

`dfb <exp1>[,<exp2>,<"string1">...]`
Equivalent to `byte <exp1>[,<exp2>,<"string1">...]`.

`dfw <exp1>[,<exp2>...]`
Equivalent to `word <exp1>[,<exp2>...]`.

`defs <exp>[,<fill>]`
Equivalent to `blk <exp>[,<fill>]`.

`dephase` Equivalent to `rend`.

`ds <exp>[,<fill>]`
Equivalent to `blk <exp>[,<fill>]`.

`dsb <exp>[,<fill>]`
Equivalent to `blk <exp>[,<fill>]`.

`dsw <exp>[,<fill>]`
Equivalent to `blkw <exp>[,<fill>]`.

`dw <exp1>[,<exp2>...]`
Equivalent to `word <exp1>[,<exp2>...]`.

`end` Assembly will terminate behind this line.
`endif` Ends a section of conditional assembly.
`el` Equivalent to `else`.
`else` Assemble the following lines when the previous `if`-condition was false.
`ei` Equivalent to `endif`. (Not available for Z80 CPU)
`endm` Ends a macro definition.
`endmac` Ends a macro definition.
`endmacro` Ends a macro definition.
`endr` Ends a repetition block.
`endrep` Ends a repetition block.
`endrepeat` Ends a repetition block.
`endstruct` Ends a structure definition.
`endstructure` Ends a structure definition.
`<symbol> eq <expression>`
 Equivalent to `<symbol> equ <expression>`.
`<symbol> equ <expression>`
 Define a new program symbol with the name `<symbol>` and assign to it the
 value of `<expression>`. Defining `<symbol>` twice will cause an error.
`extern <symbol>[,<symbol>...]`
 See `global`.
`even` Aligns to an even address. Equivalent to `align 1`.
`fail <message>`
 Show an error message including the `<message>` string. Do not generate an
 output file.
`fill <exp>`
 Equivalent to `blk <exp>,0`.
`fcb <exp1>[,<exp2>,"<string1>"...]`
 Equivalent to `byte <exp1>[,<exp2>,"<string1>"...]`.
`fcc "<string>"`
 Equivalent to `text`.
`fdb <exp1>[,<exp2>,"<string1>"...]`
 Equivalent to `word <exp1>[,<exp2>...]`.
`global <symbol>[,<symbol>...]`
 Flag `<symbol>` as an external symbol, which means that `<symbol>` is visible to
 all modules in the linking process. It may be either defined or undefined.

if <expression>
Conditionally assemble the following lines if <expression> is non-zero.

ifdef <symbol>
Conditionally assemble the following lines if <symbol> is defined.

ifndef <symbol>
Conditionally assemble the following lines if <symbol> is undefined.

ifd <symbol>
Conditionally assemble the following lines if <symbol> is defined.

ifnd <symbol>
Conditionally assemble the following lines if <symbol> is undefined.

ifeq <expression>
Conditionally assemble the following lines if <expression> is zero.

ifne <expression>
Conditionally assemble the following lines if <expression> is non-zero.

ifgt <expression>
Conditionally assemble the following lines if <expression> is greater than zero.

ifge <expression>
Conditionally assemble the following lines if <expression> is greater than zero or equal.

iflt <expression>
Conditionally assemble the following lines if <expression> is less than zero.

ifle <expression>
Conditionally assemble the following lines if <expression> is less than zero or equal.

ifused <symbol>
Conditionally assemble the following lines if <symbol> has been previously referenced in an expression or in a parameter of an opcode. Issue a warning, when <symbol> is already defined. Note that **ifused** does not work, when the symbol has only been used in the following lines of the source.

incbin <file>[,<offset>[,<nbytes>]]
Inserts the binary contents of <file> into the object code at this position. When <offset> is specified, then the given number of bytes will be skipped at the beginning of the file. The optional <nbytes> argument specifies the maximum number of bytes to be read from that file. The file will be searched first in the current directory, then in all paths defined by '-I' or **incdir** in the order of occurrence.

incdir <path>
Add another path to search for include files to the list of known paths. Paths defined with '-I' on the command line are searched first.

include <file>

Include source text of <file> at this position. The include file will be searched first in the current directory, then in all paths defined by '-I' or **incdir** in the order of occurrence.

mac <name>

Equivalent to **macro** <name>.

list

The following lines will appear in the listing file, if it was requested.

local <symbol>[,<symbol>...]

Flag <symbol> as a local symbol, which means that <symbol> is local for the current file and invisible to other modules in the linking process.

macro <name>[,<argname>...]

Defines a macro which can be referenced by <name>. The <name> may also appear at the left side of the **macro** directive, starting at the first column. The macro definition is closed by an **endm** directive. When calling a macro you may pass up to 9 arguments, separated by comma. Those arguments are referenced within the macro context as \1 to \9, or optionally by named arguments, which you have to specify in the operand. Argument \0 is set to the macro's first qualifier (mnemonic extension), when given. The special argument \@ inserts a unique id, useful for defining labels. \() may be used as a separator between the name of a macro argument and the subsequent text.

mdat <file>

Equivalent to **incbin** <file>.

nolist

The following lines will not be visible in a listing file.

org <expression>

Sets the base address for the subsequent code. This is equivalent to ***=<expression>**.

phase <expression>

Equivalent to **rorg** <expression>.

repeat <expression>

Equivalent to **rept** <expression>.

rept <expression>

Repeats the assembly of the block between **rept** and **endr** <expression> number of times. <expression> has to be positive.

reserve <exp>

Equivalent to **blk** <exp>,0.

rend

Ends a **rorg** block of label relocation. Following labels will be based on **org** again.

rorg <expression>

Relocate all labels between **rorg** and **rend** based on the new origin. Note that this directive only makes sense when generating absolute code using **org**.

section <name>[, "<attributes>"]

Starts a new section named <name> or reactivate an old one. If attributes are given for an already existing section, they must match exactly. The section's name will also be defined as a new symbol, which represents the section's start address. The "<attributes>" string may consist of the following characters:

Section Contents:

c	section has code
d	section has initialized data
u	section has uninitialized data
i	section has directives (info section)
n	section can be discarded
R	remove section at link time
a	section is allocated in memory

Section Protection:

r	section is readable
w	section is writable
x	section is executable
s	section is sharable

<symbol> **set** <expression>

Create a new symbol with the name <symbol> and assign the value of <expression>. If <symbol> is already assigned, it will contain a new value from now on.

spc <exp> Equivalent to **blk** <exp>, 0.

string "<string1>"[, "<string2>"...]

Like **text**, but adds a terminating zero-byte.

struct <name>

Defines a structure which can be referenced by <name>. Labels within a structure definition can be used as field offsets. They will be defined as local labels of <name> and can be referenced through <name>.<label>. All directives are allowed, but instructions will be ignored when such a structure is used. Data definitions can be used as default values when the structure is used as initializer. The structure name, <name>, is defined as a global symbol with the structure's size. A structure definition is ended by **endstruct**.

structure <name>

Equivalent to **struct** <name>.

text "<string>"

Places a single string constant operands into successive bytes of memory in the current section. The string delimiters may be any printable ASCII character.

weak <symbol>[,<symbol>...]
 Flag <symbol> as a weak symbol, which means that <symbol> is visible to all modules in the linking process and may be replaced by any global symbol with the same name. When a weak symbol remains undefined its value defaults to 0.

wor <exp1>[,<exp2>...]
 Equivalent to **word** <exp1>[,<exp2>...].

wrd Increases the program counter by two. Equivalent to **blkw** 1,0.

word <exp1>[,<exp2>...]
 Assign the values of the operands into successive 16-bit words of memory in the current section, using the endianness of the target CPU.

xdef <symbol>[,<symbol>...]
 See **global**.

xlib <symbol>[,<symbol>...]
 See **global**.

xref <symbol>[,<symbol>...]
 See **global**.

5.5 Structures

The oldstyle syntax is able to manage structures. Structures can be defined in two ways:

```
mylabel struct[ure]
    <fields>
endstruct[ure]
```

or:

```
struct[ure] mylabel
    <fields>
endstruct[ure]
```

Any directive is allowed to define the structure fields. Labels can be used to define offsets into the structure. The initialized data is used as default value, whenever no value is given for a field when the structure is referenced.

Some examples of structure declarations:

```
    struct point
x      db 4
y      db 5
z      db 6
    endstruct
```

This will create the following labels:

```
point.x  ; 0    offsets
point.y  ; 1
point.z  ; 2
point    ; 3    size of the structure
```

The structure can be used by optionally redefining the fields value:

```
point1 point
point2 point 1, 2, 3
point3 point ,,4
```

is equivalent to

```
point1
    db 4
    db 5
    db 6

point2
    db 1
    db 2
    db 3

point3
    db 4
    db 5
    db 4
```

5.6 Known Problems

Some known problems of this module at the moment:

- Addresses assigned to `org` or to the current pc symbol `'*`' (on the z80 the pc symbol is `'$'`) must be constant.
- Expressions in an `if` directive must be constant.

5.7 Error Messages

This module has the following error messages:

- 1001: syntax error
- 1002: invalid extension
- 1003: no space before operands
- 1004: too many closing parentheses
- 1005: missing closing parentheses
- 1006: missing operand
- 1007: garbage at end of line
- 1008: `%c` expected
- 1009: invalid data operand
- 1010: `,` expected
- 1011: identifier expected
- 1012: illegal escape sequence `\%c`
- 1013: expression must be a constant
- 1014: repeatedly defined symbol
- 1015: `endif` without `if`
- 1016: `if` without `endif`

- 1017: maximum if-nesting depth exceeded (%d levels)
- 1018: else without if
- 1019: unexpected endr without macro
- 1020: unexpected endr without rept
- 1021: cannot open binary file "%s"
- 1022: symbol <%s> already defined with %s scope
- 1023: alignment too big
- 1024: label <%s> had already been defined
- 1025: skipping instruction in struct init
- 1026: last %d bytes of string constant had been cut

6 Simple binary output module

This chapter describes the simple binary output module which can be selected with the ‘-Fbin’ option.

6.1 Legal

This module is copyright in 2002,2008 by Volker Barthelmann.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

6.2 Additional options for this version

‘-cbm-prg’

Writes a Commodore PRG header in front of the output file, which consists of two bytes in little-endian order, defining the load address of the program.

6.3 General

This output module outputs the contents of all sections as simple binary data without any header or additional information. When there are multiple sections, they must not overlap. Gaps between sections are filled with zero bytes. Undefined symbols are not allowed.

6.4 Known Problems

Some known problems of this module at the moment:

- None.

6.5 Error Messages

This module has the following error messages:

- 3001: sections must not overlap
- 3007: undefined symbol <%s>

7 Test output module

This chapter describes the test output module which can be selected with the ‘**-Ftest**’ option.

7.1 Legal

This module is copyright in 2002 by Volker Barthelmann.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

7.2 Additional options for this version

This output module provides no additional options.

7.3 General

This output module outputs a textual description of the contents of all sections. It is mainly intended for debugging.

7.4 Restrictions

None.

7.5 Known Problems

Some known problems of this module at the moment:

- None.

7.6 Error Messages

This module has the following error messages:

- None.

8 ELF output module

This chapter describes the ELF output module which can be selected with the ‘**-Felf**’ option.

8.1 Legal

This module is copyright in 2002-2011 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

8.2 Additional options for this version

None.

8.3 General

This output module outputs the **ELF** (Executable and Linkable Format) format, which is a portable object file format which works for a variety of 32- and 64-bit operating systems.

8.4 Restrictions

The **ELF** output format, as implemented in `vasm`, currently supports the following architectures:

- PowerPC
- M68k
- ARM
- i386
- x86_64

The supported relocation types depend on the selected architecture.

8.5 Known Problems

Some known problems of this module at the moment:

- None.

8.6 Error Messages

This module has the following error messages:

- 3002: output module doesn’t support cpu <name>
- 3003: write error
- 3005: reloc type <m>, size <n>, mask <mask> (symbol <sym> + <offset>) not supported
- 3006: reloc type <n> not supported

9 a.out output module

This chapter describes the a.out output module which can be selected with the ‘**-Faout**’ option.

9.1 Legal

This module is copyright in 2008-2010 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

9.2 Additional options for this version

‘**-mid=<machine id>**’

Sets the MID field of the a.out header to the specified value. The MID defaults to 2 (Sun020 big-endian) for M68k and to 100 (PC386 little-endian) for x86.

9.3 General

This output module outputs the **a.out** (assembler output) format, which is an older 32-bit format for Unix-like operating systems, originally invented by AT&T.

9.4 Restrictions

The **a.out** output format, as implemented in vasm, currently supports the following architectures:

- M68k
- i386

The following standard relocations are supported by default:

- absolute, 8, 16, 32 bits
- pc-relative, 8, 16, 32 bits
- base-relative

Standard relocations occupy 8 bytes and don’t include an addend, so they are not suitable for most RISC CPUs. The extended relocations format occupies 12 bytes and also allows more relocation types.

9.5 Known Problems

Some known problems of this module at the moment:

- Support for stab debugging symbols is still missing.
- The extended relocation format is not supported.

9.6 Error Messages

This module has the following error messages:

- 3004: section attributes <attr> not supported
- 3008: output module doesn't allow multiple sections of the same type

10 TOS output module

This chapter describes the TOS output module which can be selected with the ‘**-Ftos**’ option.

10.1 Legal

This module is copyright in 2009-2014 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

10.2 Additional options for this version

‘**-monst**’ Write Devpac "MonST"-compatible symbols.

‘**-tos-flags=<flags>**’

 Sets the flags field in the TOS file header. Defaults to 0. Overwrites a TOS flags definition in the assembler source.

10.3 General

This module outputs the TOS executable file format, which is used on Atari 16/32-bit computers with 68000 up to 68060 CPU. The symbol table uses the DRI format.

10.4 Restrictions

- All symbols must be defined, otherwise the generation of the executable fails. Unknown symbols are listed by vasm.
- The only relocations allowed in this format are 32-bit absolute.

Those are restrictions of the output format, not of vasm.

10.5 Known Problems

Some known problems of this module at the moment:

- None.

10.6 Error Messages

This module has the following error messages:

- 3004: section attributes <attr> not supported
- 3005: reloc type %d, size %d, mask 0x%lx (symbol %s + 0x%lx) not supported
- 3006: reloc type %d not supported
- 3007: undefined symbol <%s>
- 3008: output module doesn’t allow multiple sections of the same type

11 vobj output module

This chapter describes the simple binary output module which can be selected with the ‘-Fvobj’ option.

11.1 Legal

This module is copyright in 2002-2011 by Volker Barthelmann.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

11.2 Additional options for this version

None.

11.3 General

This output module outputs the `vobj` object format, a simple portable proprietary object file format of `vasm`.

As this format is not yet fixed, it is not described here.

11.4 Restrictions

None.

11.5 Known Problems

Some known problems of this module at the moment:

- None.

11.6 Error Messages

This module has the following error messages:

- None.

12 Amiga output module

This chapter describes the AmigaOS hunk-format output module which can be selected with the ‘-Fhunk’ option to generate objects and with the ‘-Fhunkexe’ option to generate executable files.

12.1 Legal

This module is copyright in 2002-2014 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

12.2 Additional options for this version

‘-kick1hunks’

Use only those hunk types and external reference types which have been valid at the time of Kickstart 1.x for compatibility with old assembler sources and old linkers. For example: no longer differentiate between absolute and relative references.

These options are valid for the **hunkexe** module only:

‘-databss’

Try to shorten sections in the output file by removing zero words without relocation from the end. This technique is only supported by AmigaOS 2.0 and higher.

12.3 General

This output module outputs the **hunk** object (standard for **M68k** and extended for **PowerPC**) and **hunkexe** executable format, which is a proprietary file format used by AmigaOS and WarpOS.

The **hunkexe** module will generate directly executable files, without the need for another linker run. But you have to make sure that there are no undefined symbols, common symbols, or unusual relocations (e.g. small data) left.

It is allowed to define sections with the same name but different attributes. They will be regarded as different entities.

12.4 Restrictions

The **hunk**/**hunkexe** output format is only intended for **M68k** and **PowerPC** cpu modules and will abort when used otherwise.

The **hunk** module supports the following relocation types:

- absolute, 32-bit
- absolute, 16-bit

- absolute, 8-bit
- relative, 8-bit
- relative, 14-bit (mask 0xffff) for PPC branch instructions.
- relative, 16-bit
- relative, 24-bit (mask 0xffffff) for PPC branch instructions.
- relative, 32-bit
- base-relative, 16-bit
- common symbols are supported as 32-bit absolute and relative references

The `hunkexe` module supports absolute 32-bit relocations only.

12.5 Known Problems

Some known problems of this module at the moment:

- The `hunkexe` module won't process common symbols and allocates them in a BSS section. Use a real linker for that.

12.6 Error Messages

This module has the following error messages:

- 3001: multiple sections not supported by this format
- 3002: output module doesn't support cpu <name>
- 3003: write error
- 3004: section attributes <attr> not supported
- 3005: reloc type <m>, size <n>, mask <mask> (symbol <sym> + <offset>) not supported
- 3006: reloc type <n> not supported

13 m68k cpu module

This chapter documents the backend for the Motorola M68k/CPU32/ColdFire microprocessor family.

13.1 Legal

This module is copyright in 2002-2014 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

13.2 Additional options for this module

This module provides the following additional options:

13.2.1 CPU selections

- '-m68000' Generate code for the MC68000 CPU.
- '-m68008' Generate code for the MC68008 CPU.
- '-m68010' Generate code for the MC68010 CPU.
- '-m68020' Generate code for the MC68020 CPU.
- '-m68030' Generate code for the MC68030 CPU.
- '-m68040' Generate code for the MC68040 CPU.
- '-m68060' Generate code for the MC68060 CPU.
- '-m68020up'
 - Generate code for the MC68020-68060 CPU. Be careful with instructions like PFLUSHA, which exist on 68030 and 68040/060 with a different opcode (vasm will use the 040/060 version).
- '-mcpu32' Generate code for the CPU32 family (MC6833x, MC6834x, etc.).
- '-mcf5...'
- '-m5...'
 - Generate code for a ColdFire family CPU. The following types are recognized: 5202, 5204, 5206, 520x, 5206e, 5207, 5208, 5210a, 5211a, 5212, 5213, 5214, 5216, 5224, 5225, 5232, 5233, 5234, 5235, 523x, 5249, 5250, 5253, 5270, 5271, 5272, 5274, 5275, 5280, 5281, 528x, 52221, 52553, 52230, 52231, 52232, 52233, 52234, 52235, 52252, 52254, 52255, 52256, 52258, 52259, 52274, 52277, 5307, 5327, 5328, 5329, 532x, 5372, 5373, 537x, 53011, 53012, 53013, 53014, 53015, 53016, 53017, 5301x, 5407, 5470, 5471, 5472, 5473, 5474, 5475, 547x, 5480, 5481, 5482, 5483, 5484, 5485, 548x, 54450, 54451, 54452, 54453, 5445x.
- '-mcfv2' Generate code for the V2 ColdFire core. This option selects ISA_A (no hardware division or MAC), which is the most limited ISA supported by 5202, 5204 and 5206. All other ColdFire chips are backwards compatible to V2.

- `'-mcfv3'` Generate code for the V3 ColdFire core. This option selects ISA_A+, hardware division MAC and EMAC instructions, which are supported by nearly all V3 CPUs, except the 5307.
- `'-mcfv4'` Generate code for the V4 ColdFire core. This option selects ISA_B and MAC as supported by the 5407.
- `'-mcfv4e'` Generate code for the V4e ColdFire core. This option selects ISA_B, USP-, FPU-, MAC- and EMAC-instructions (no hardware division) as supported by all 547x and 548x CPUs.
- `'-m68851'` Generate code for the MC68851 MMU. May be used in combination with another -m option.
- `'-m68881'` Generate code for the MC68881 FPU. May be used in combination with another -m option.
- `'-m68882'` Generate code for the MC68882 FPU. May be used in combination with another -m option.

13.2.2 Optimization options

- `'-no-opt'` Disable all optimizations. Can be seen as a main switch to ignore all other optimization options on the command line and in the source.
- `'-opt-allbra'`

When specified the assembler will also try to optimize branch instructions which already have a valid size extension. This option is automatically enabled in `'-phxass'` mode.
- `'-opt-brajump'`

Translate relative branch instructions, whose destination is in a different section, into absolute jump instructions.
- `'-opt-clr'`

Enables optimization from `MOVE #0,<ea>` into `CLR <ea>` for the MC68000. Note that `CLR` will execute a read-modify-write cycle on the 68000, so it is disabled by default. With 68010 and higher this is a generic standard optimization.
- `'-opt-fconst'`

Floating point constants are loaded with the lowest precision possible. This means that `FMOVE.D #1.0,FP0` would be optimized to `FMOVE.S #1.0,FP0`, because it is faster and shorter at the same precision. The optimization will be performed on all FPU instructions with immediate addressing mode. When an `FDIV`-family instruction (`FSDIV`, `FDDIV`, `FSGLDIV`) is detected it will additionally be checked if the immediate constant is a power of 2 and then converted into `FMUL #1/c,FPn`.
- `'-opt-lsl'`

Allows optimization of `LSL #1` into `ADD`. It is also needed to optimize `ASL #2` and `LSL #2` into two `ADD` instructions (together with `'-opt-speed'`). These optimizations may modify the V-flag, which might not be intended.

‘-opt-movem’

Enables optimization from `MOVEM <ea>, Rn` into `MOVE <ea>, Rn` (or the other way around). This optimization will modify the flags, when the destination is no address register.

‘-opt-mul’

Immediate multiplication factors, which are a power of two (from 2 to 256), are optimized to shifts. Multiplications with zero are replaced by a `MOVEQ #0, Dn`, with -1 are replaced by a `NEG.L Dn` and with 1 by `EXT.L Dn` or `TST.L Dn` (long-form). Not all optimizations are available for all cpu types (e.g. `MULU.W` can only be optimized on ColdFire by using the `MVZ.W` instruction. This optimization will leave the flags in a different state as can normally be expected after a multiplication instruction, and the size of the optimized code may be bigger than before in a few situations (e.g. `MULS.W #4, Dn`). The latter will additionally require the ‘-opt-speed’ flag.

‘-opt-div’

Unsigned immediate divisors, which are a power of two (from 2 to 256), are optimized to shifts. Divisions by 1 are replaced by `TST.L Dn` (32-bit) or `MVZ.W Dn, Dn` (16-bit, ColdFire only). Divisions by -1 are replaced by `NEG.L Dn` (32-bit) or by a combination of `NEG.W Dn` and `MVZ.W Dn, Dn` (16-bit, ColdFire only). This optimization will leave the flags in a different state as can normally be expected after a division instruction.

‘-opt-pea’

Enables optimization from `MOVE #x, -(SP)` into `PEA x`. This optimization will leave the flags unmodified, which might not be intended.

‘-opt-speed’

Optimize for speed, even if this would increase code size. For example it enables optimization of `ASL.W #2, Dn` into two `ADD.W Dn, Dn` instructions. Or `MULS.W #-4, Dn` into `EXT.L Dn + ASL.L #2, Dn + NEG.L Dn`. Generally the assembler will never optimize a single into multiple instructions without this option.

‘-opt-st’ Enables optimization from `MOVE.B #-1, <ea>` into `ST <ea>`. This optimization will leave the flags unmodified, which might not be intended.

‘-sc’ All `JMP` and `JSR` instructions to external labels will be converted into 16-bit PC-relative jumps.

‘-showcrit’

Print all critical optimizations which have side effects. Among those are `-opt-lsl`, `-opt-mul`, `-opt-st`, `-opt-pea`, `-opt-movem` and `-opt-clr`.

‘-showopt’

Print all optimizations and translations vasm is doing (same as `opt ow+`).

In its default setting (no ‘-devpac’ or ‘-phxass’ option) vasm performs the following optimizations:

- Absolute to PC-relative.
- Branches without explicit size.

- Displacements (32 to 16 bit, (0,An) to (An), etc).
- Optimize floating point constants to the lowest possible precision.
- Many instruction optimizations which are safe.

13.2.3 Other options

‘-conv-brackets’

Brackets (‘[’ and ‘]’) in an operand are automatically converted into parentheses (‘(’ and ‘)’) as long as the CPU is 68000 or 68010. This is a compatibility option for some old assemblers.

‘-devpac’ All options are initially set to be Devpac compatible. Which means that all optimizations are disabled, no debugging symbols will be written and vasm will warn about any optimization being done. Shift-right operations are performed using an unsigned 32-bit value. Other options are the same as vasm’s defaults. The symbol `__G2` is defined, which contains information about the selected cpu type. It will also automatically enable ‘-guess-ext’.

‘-elfregs’

Register names are preceded by a ‘%’ to prevent confusion with symbol names.

‘-guess-ext’

Accept illegal size extensions for an instruction, as long as the instruction is unsized or there is just a single size possible. This is the default setting in PhxAss and Devpac compatibility mode.

‘-phxass’ PhxAss-compatibility mode. The "current PC symbol" (e.g. * in mot-syntax module) is set to the instruction’s address + 2 whenever an instruction is parsed. According to the current cpu setting the symbols `__CPU`, `__FPU` and `__MMU` are defined. `JMP/JSR (label,PC)` will never be optimized (into a branch, for example). It will also automatically enable ‘-opt-allbra’ and ‘-guess-ext’.

‘-rangewarnings’

Values which are out of range usually produce an error. With this option the errors 2026, 2030, 2033 and 2037 will be displayed as a warning, allowing the user to create an object file.

‘-sdreg=<n>’

Set the small data base register to An. <n> is valid between 2 and 6.

13.3 General

This backend accepts M68k and CPU32 instructions as described in Motorola’s M68000 family Programmer’s Reference Manual. Additionally it supports ColdFire instructions as described in Motorola’s ColdFire Microprocessor Family Programmer’s Reference Manual. The syntax for the scale factor in ColdFire MAC instructions is << for left- and >> for right-shift. The scale factor may be appended as an optional operand, when needed. Example: `mac d0.l,d1.u,<<.`

The mask flag in MAC instructions is written as & and is appended directly to the effective address operand. Example: `mac d0,d1,(a0)&,d2.`

The target address type is 32bit.

Default alignment for instructions is 2 bytes. The default alignment for data is 2 bytes, when the data size is larger than 8 bits.

Depending on the selected cpu type the `__VASM` symbol will have a value defined by the following bits:

bit 0	MC68000 instruction set. Also used by MC6830x, MC68322, MC68356.
bit 1	MC68010 instruction set.
bit 2	MC68020 instruction set.
bit 3	MC68030 instruction set.
bit 4	MC68040 instruction set.
bit 5	MC68060 instruction set.
bit 6	MC68881 or MC68882 FPU.
bit 7	MC68851 PMMU.
bit 8	CPU32. Any MC6833x or MC6834x CPU.
bit 9	ColdFire ISA_A.
bit 10	ColdFire ISA_A+.
bit 11	ColdFire ISA_B.
bit 12	ColdFire ISA_C.
bit 13	ColdFire hardware division support.
bit 14	ColdFire MAC instructions.
bit 15	ColdFire enhanced MAC instructions.
bit 16	ColdFire USP register.
bit 17	ColdFire FPU instructions.
bit 18	ColdFire MMU instructions.

13.4 Extensions

This backend extends the selected syntax module by the following directives:

`.sdreg <An>`

Equivalent to `near <An>`.

`basereg <expression>,<An>`

Starts a block of base-relative addressing through register `An` (remember that A7 is not allowed as a base register). The programmer has to make sure that `<expression>` is placed into `An` first, while the assembler automatically subtracts `<expression>`, which is usually a program label with an optional offset, from each displacement in a `(d,An)` addressing mode. `basereg` has priority over the `near` directive. Its effect can be suspended with the `endb` directive. It is allowed to use several base registers in parallel.

- cpu32** Generate code for the CPU32 family.
- endb <An>** Ends a **basereg** block and suspends its effect onto the specified base register **An**. It may be reused with a different base expression thereafter (refer to **basereg**).
- far** Disables small data (base-relative) mode. All data references will be absolute.
- fpu <cpID>**
 Enables 68881/68882 FPU code generation. The <cpID> is inserted into the FPU instructions to select the correct coprocessor. Note that <cpID> is always 1 for the on-chip FPUs in the 68040 and 68060. A <cpID> of zero will disable FPU code generation.
- initnear** Initializes the selected small data register. In contrast to PhxAss, where this directive comes from, just a reference to **_LinkerDB** is generated, which has to be resolved by a linker.
- machine <cpu_type>**
 Makes the assembler generate code for <cpu_type>, which can be the following: 68000, 68010, 68020, 68030, 68040, 68060, 68851, 68881, 68882, **cpu32**. And various ColdFire CPUs, starting with 5....
- mc68000** Generate code for the MC68000 CPU.
- mc68010** Generate code for the MC68010 CPU.
- mc68020** Generate code for the MC68020 CPU.
- mc68030** Generate code for the MC68030 CPU.
- mc68040** Generate code for the MC68040 CPU.
- mc68060** Generate code for the MC68060 CPU.
- mcf5...** Generate code for a ColdFire CPU. The recognized models are listed in the assembler-options section.
- near [<An>]**
 Enables small data (base-relative) mode and sets the base register to **An**. **near** without an argument will reactivate a previously defined small data mode, which might be switched off by a **far** directive.
- near code** All JMP and JSR instructions to external labels will be converted into 16-bit PC-relative jumps. The small code mode can be switched off by a **far** directive.
- opt <option>[,<option>...]**
 Sets Devpac-compatible options. When option **'-phxass'** is given, then it will parse PhxAss options (which is discouraged, so there is no detailed description here). The supported Devpac2-style options are always suffixed by a + or - to enable or disable the option:
- a** Automatically optimize absolute to PC-relative references. Default is off in Devpac-comptability mode, otherwise on.
 - c** Case-sensitivity for all symbols, instructions and macros. Default is on.

d	Include all symbols for debugging in the output file. Default is off in Devpac-compatibility mode, otherwise on.
o	Enable all optimizations (o1 to o12), or disable all optimizations. Default is that all are disabled in Devpac-compatibility mode and enabled otherwise. When running in native vasm mode this option will also control the following safe vasm-specific optimizations (see below): og, of, oj.
o1	Optimize branches without an explicit size extension.
o2	Standard displacement optimizations (e.g. (0,An) -> (An)).
o3	Optimize absolute addresses to short words.
o4	Optimize move.l to moveq.
o5	Optimize add #x and sub #x into their quick forms.
o6	No effect in vasm.
o7	Convert bra.b to nop, when branching to the next instruction.
o8	Optimize 68020+ base displacements to 16 bit.
o9	Optimize 68020+ outer displacements to 16 bit.
o10	Optimize add/sub #x,An to lea.
o11	Optimize lea (d,An),An to addq/subq.
o12	Optimize <op>.l #x,An to <op>.w #x,An.
ow	Show all optimizations being performed. Default is on in Devpac-compatibility mode, otherwise off.
p	Check if code is position independant. This will cause an error on each relocation being required. Default is off.
s	Include symbols in listing file. Default is on.
t	Check size and type of all expressions. Default is on.
w	Show assembler warnings. Default is on.
x	Ignored, as it has very different meaning in the Atari and Amiga versions of Devpac. On Atari it enabled an extended debugging format, which allowed symbols with more than 8 character (vasm has no limitation here, so this is useless). On Amiga it made the assembler include only those symbols which were exported by xdef. So x+ would be the same as d-.

Also the following Devpac3-style options are supported:

autopc	Corresponds to a+.
case	Corresponds to c+.
chkpc	Corresponds to p+.

<code>debug</code>	Corresponds to <code>d+</code> .
<code>syntab</code>	Corresponds to <code>s+</code> .
<code>type</code>	Corresponds to <code>t+</code> .
<code>warn</code>	Corresponds to <code>w+</code> .
<code>xdebug</code>	Corresponds to <code>x+</code> .
<code>noautopc</code>	Corresponds to <code>a-</code> .
<code>nocase</code>	Corresponds to <code>c-</code> .
<code>nochkpc</code>	Corresponds to <code>p-</code> .
<code>nodebug</code>	Corresponds to <code>d-</code> .
<code>nosyntab</code>	Corresponds to <code>s-</code> .
<code>notype</code>	Corresponds to <code>t-</code> .
<code>nowarn</code>	Corresponds to <code>w-</code> .
<code>noxdebug</code>	Corresponds to <code>x-</code> .

`p=<type>[/<type>]`

Sets the CPU type to any model vasm supports (original Devpac3 only allowed 68000-68040, 68332, 68881, 68882 and 68851).

The following options are vasm specific and should not be used when writing portable source. Using `opt o+` in Devpac mode does not enable any of these options.

<code>oc</code>	Enable optimizations to CLR (refer to <code>-opt-clr</code>).
<code>od</code>	Enable optimization of divisions into shifts (refer to <code>-opt-div</code>).
<code>of</code>	Enable immediate float constant optimizations (refer to <code>-opt-fconst</code>).
<code>og</code>	Enable generic vasm optimizations. All optimizations which cannot be controlled by another option.
<code>oj</code>	Enable branch to jump translations (refer to <code>-opt-brajmp</code>).
<code>ol</code>	Enable shift optimizations to ADD (refer to <code>-opt-lsl</code>).
<code>om</code>	Enable MOVEM optimizations (refer to <code>-opt-movem</code>).
<code>op</code>	Enable optimizations to PEA (refer to <code>-opt-pea</code>).
<code>os</code>	Optimize for speed before optimizing for size (refer to <code>-opt-speed</code>).
<code>ot</code>	Enable optimizations to ST (refer to <code>-opt-st</code>).
<code>ox</code>	Enable optimization of multiplications into shifts (refer to <code>-opt-mul</code>).

The default state is 'off' for all those vasm specific options.

The following directives are only available for the Motorola syntax module:

<symbol> equr <Rn>

Define a new symbol named <symbol> and assign the data or address register Rn, which can be used from now on in operands. Note that a register symbol must be defined before it can be used!

<symbol> equrl <reglist>

Equivalents to <symbol> reg <reglist>.

<symbol> fequr <FPn>

Define a new symbol named <symbol> and assign the FPU register FPn, which can be used from now on in operands. Note that a register symbol must be defined before it can be used!

<symbol> fequrl <reglist>

Equivalents to <symbol> freg <reglist>.

<symbol> freg <reglist>

Defines a new symbol named <symbol> and assign the FPU register list <reglist> to it. Registers in a list must be separated by a slash (/) and ranges or registers can be defined by using a hyphen (-). Examples for valid FPU register lists are: fp0-fp7, fp1-3/fp5/fp7, fpiar/fpcr.

<symbol> reg <reglist>

Defines a new symbol named <symbol> and assign the register list <reglist> to it. Registers in a list must be separated by a slash (/) and ranges or registers can be defined by using a hyphen (-). Examples for valid register lists are: d0-d7/a0-a6, d3-6/a0/a1/a4-5.

13.5 Optimizations

This backend performs the following operand optimizations:

- (0,An) optimized to (An).
- (d16,An) translated to (bd32,An,ZDn.w), when d16 is not between -32768 and 32767 and the selected CPU allows it (68020 up or CPU32).
- (d16,PC) translated to (bd32,PC,ZDn.w), when d16 is not between -32768 and 32767 and the selected CPU allows it (68020 up or CPU32).
- (d8,An,Rn) translated to (bd,An,Rn), when d8 is not between -128 and 127 and the selected CPU allows it (68020 up or CPU32).
- (d8,PC,Rn) translated to (bd,PC,Rn), when d8 is not between -128 and 127 and the selected CPU allows it (68020 up or CPU32).
- <exp>.l optimized to <exp>.w, when <exp> is absolute and between -32768 and 32767.
- <exp>.w translated to <exp>.l, when <exp> is a program label or absolute and not between -32768 and 32767.
- (0,An,...) optimized to (An,...) (which means the base displacement will be suppressed). This allows further optimization to (An), when the index is suppressed.
- (bd16,An,...) translated to (bd32,An,...), when bd16 is not between -32768 and 32767.
- (bd32,An,...) optimized to (bd16,An,...), when bd16 is between -32768 and 32767.

- (bd32,An,ZRn) optimized to (d16,An), when bd32 is between -32768 and 32767, and the index is suppressed (zero-Rn).
- (An,ZRn) optimized to (An), when the index is suppressed.
- (0,PC,...) optimized to (PC,...) (which means the base displacement will be suppressed).
- (bd16,PC,...) translated to (bd32,PC,...), when bd16 is not between -32768 and 32767.
- (bd32,PC,...) optimized to (bd16,PC,...), when bd16 is between -32768 and 32767.
- (bd32,PC,ZRn) optimized to (d16,PC), when bd32 is between -32768 and 32767, and the index is suppressed (zero-Rn).
- ([0,Rn,...],...) optimized to ([An,...],...) (which means the base displacement will be suppressed).
- ([bd16,Rn,...],...) translated to ([bd32,An,...],...), when bd16 is not between -32768 and 32767.
- ([bd32,Rn,...],...) optimized to ([bd16,An,...],...), when bd32 is between -32768 and 32767.
- ([...],0) optimized to ([...]) (which means the outer displacement will be suppressed).
- ([...],od16) translated to ([...],od32), when od16 is not between -32768 and 32767.
- ([...],od32) translated to ([...],od16), when od32 is between -32768 and 32767.

Note that an operand optimization will only take place when a displacement's size was not enforced by the programmer (e.g. (4.1,a0))!

This backend performs the following instruction optimizations:

- <op>.L #x,An optimized to <op>.W #x,An, when x is between -32768 and 32767.
- ADD.? #x,<ea> optimized to ADDQ.? #x,<ea>, when x is between 1 and 8.
- ADD.? #x,<ea> optimized to SUBQ.? #x,<ea>, when x is between -1 and -8.
- ADDA.? #0,An and SUBA.? #0,An will be deleted.
- ADDA.? #x,An optimized to LEA (x,An),An, when x is between -32768 and 32767.
- ANDI.L #\$ff,Dn optimized to MVZ.B Dn,Dn, for ColdFire ISA_B/C.
- ANDI.L #\$ffff,Dn optimized to MVZ.W Dn,Dn, for ColdFire ISA_B/C.
- ANDI.? #0,<ea> optimized to CLR.? <ea>, when allowed by the option -opt-clr or a different CPU than the MC68000 was selected.
- ANDI.? #-1,<ea> optimized to TST.? <ea>.
- ASL.? #1,Dn optimized to ADD.? Dn,Dn for 68000 and 68010.
- ASL.? #2,Dn optimized into a sequence of two ADD.? Dn,Dn for 68000 and 68010, when the operation size is either byte or word and the options -opt-speed and -opt-lsl are given.
- B<cc> <label> translated into a combination of B!<cc> **8 and JMP <label>, when <label> is not defined in the same section (and option -opt-brajmp is given), or outside the range of -32768 to 32767 bytes from the current address when the selected CPU is not 68020 up, CPU32 or ColdFire ISA_B/C.

- B<cc> <label> is automatically optimized to 8-bit, 16-bit or 32-bit (68020 up, CPU32, MCF5407 only), whatever fits best. When the selected CPU doesn't support 32-bit branches it will try to change the conditional branch into a B<!cc> ++8 and JMP <label> sequence.
- BRA <label> translated to JMP <label>, when <label> is not defined in the same section (and option `-opt-brajmp` is given), or outside the range of -32768 to 32767 bytes from the current address when the selected CPU is not 68020 up, CPU32 or ColdFire ISA_B/C.
- BSR <label> translated to JSR <label>, when <label> is not defined in the same section (and option `-opt-brajmp` is given), or outside the range of -32768 to 32767 bytes from the current address when the selected CPU is not 68020 up, CPU32 or ColdFire ISA_B/C.
- <cp>B<cc> <label> is automatically optimized to 16-bit or 32-bit, whatever fits best. <cp> means coprocessor and is P for the PMMU and F for the FPU.
- CLR.L Dn optimized to MOVEQ #0,Dn.
- CMP.? #0,<ea> optimized to TST.? <ea>. The selected CPU type must be MC68020 up, ColdFire or CPU32 to support address register direct as effective address (<ea>).
- DIVS.W/DIVU.W #1,Dn optimized to MVZ.W Dn,Dn, for ColdFire ISA_B/C (`-opt-div`).
- DIVS.W #-1,Dn optimized to the sequence of NEG.W Dn and MVZ.W Dn,Dn (`-opt-div` and `-opt-speed`).
- DIVS.L/DIVU.L #1,Dn optimized to TST.L Dn (`-opt-div`).
- DIVS.L #-1,Dn optimized to NEG.L Dn (`-opt-div`).
- DIVU.L #2..256,Dn optimized to LSR.L #x,Dn (`-opt-div`).
- EORI.? #-1,<ea> optimized to NOT.? <ea>.
- EORI.? #0,<ea> optimized to TST.? <ea>.
- FMOVEM.? <reglist> is deleted, when the register list was empty.
- FxDIV.? #m,FPn optimized to FxMUL.? #1/m,FPn when m is a power of 2 and option `-opt-fconst` is given.
- JMP <label> optimized to BRA.? <label>, when <label> is defined in the same section and in the range of -32768 to 32767 bytes from the current address. Note that JMP (<lab>,PC) is never optimized.
- JSR <label> optimized to BSR.? <label>, when <label> is defined in the same section and in the range of -32768 to 32767 bytes from the current address. Note that JSR (<lab>,PC) is never optimized.
- LEA 0,An optimized to SUBA.L An,An.
- LEA (0,An),An and LEA (An),An will be deleted.
- LEA (d,An),An is optimized to ADDQ.L #d,An when d is between 1 and 8 and to SUBQ.L #-d,An when d is between -1 and -8.
- LEA (d,Am),An will be translated into a combination of MOVEA and ADDA.L for 68000 and 68010, when d is lower than -32768 or higher than 32767. The MOVEA will be omitted when Am and An are identical. Otherwise `-opt-speed` is required.
- LINK.L An,#x optimized to LINK.W An,#x, when x is between -32768 and 32767.

- `LINK.W An,#x` translated to `LINK.L An,#x`, when `x` is not between -32768 and 32767 and selected CPU supports this instruction.
- `LSL.? #1,Dn` optimized to `ADD.? Dn,Dn` for 68000 and 68010, when option `-opt-lsl` is given.
- `LSL.? #2,Dn` optimized into a sequence of two `ADD.? Dn,Dn` for 68000 and 68010, when the operation size is either byte or word and the options `-opt-speed` and `-opt-lsl` are given.
- `MOVE.? #0,<ea>` optimized to `CLR.? <ea>`, when allowed by the option `-opt-clr` or a different CPU than the MC68000 was selected.
- `MOVE.? #x,-(SP)` optimized to `PEA x`, when allowed by the option `-opt-pea`. The move-size must not be byte (`.b`).
- `MOVE.B #-1,<ea>` optimized to `ST <ea>`, when allowed by the option `-opt-st`.
- `MOVE.L #x,Dn` optimized to `MOVEQ #x,Dn`, when `x` is between -128 and 127.
- `MOVE.L #x,<ea>` optimized to `MOV3Q #x,<ea>`, for ColdFire ISA_B and ISA_C, when `x` is -1 or between 1 and 7.
- `MOVEA.? #0,An` optimized to `SUBA.L An,An`.
- `MOVEA.L #x,An` optimized to `MOVEA.W #x,An`, when `x` is between -32768 and 32767.
- `MOVEA.L #label,An` optimized to `LEA label,An`, which could allow further optimization to `LEA label(PC),An`.
- `MOVEM.? <reglist>` is deleted, when the register list was empty.
- `MOVEM.? <ea>,An` optimized to `MOVE.? <ea>,An`, when the register list only contains a single address register.
- `MOVEM.? <ea>,Rn` optimized to `MOVE.? <ea>,Rn` and `MOVEM.? Rn,<ea>` optimized to `MOVE.? Rn,<ea>`, when allowed by the option `-opt-movem` or when just loading an address register.
- `MOVEM.? <ea>,Rm/Rn` and `MOVEM.? Rm/Rn,<ea>` are optimized into a sequence of two `MOVE` for all cpus except 68000 and 68010. Complex addressing modes with displacements or addresses are optimized for 68040 only. Has to be enabled by the options `-opt-movem` and `-opt-speed`.
- `MULS.?/MULU.? #0,Dn` optimized to `MOVEQ #0,Dn` (`-opt-mul`).
- `MULS.?/MULU.? #1,Dn` is deleted (`-opt-mul`).
- `MULS.W #-1,Dn` optimized to the sequence `EXT.L Dn` and `NEG.L Dn` (`-opt-mul` and `-opt-speed`).
- `MULS.L #-1,Dn` optimized to `NEG.L Dn` (`-opt-mul`).
- `MULS.W #2..256,Dn` optimized to the sequence `EXT.L Dn` and `ASL.L #x,Dn` (`-opt-mul` and `-opt-speed`).
- `MULS.W #-2..-256,Dn` optimized to the sequence `EXT.L Dn`, `ASL.L #x,Dn` and `NEG.L Dn` (`-opt-mul` and `-opt-speed`).
- `MULS.L #2..256,Dn` optimized to `ASL.L #x,Dn` (`-opt-mul`).
- `MULS.L #-2..-256,Dn` optimized to the sequence `ASL.L #x,Dn` and `NEG.L Dn` (`-opt-mul` and `-opt-speed`).

- MULU.W #2..256,Dn optimized to the sequence MVZ.W Dn,Dn and ASL.L #x,Dn for Cold-Fire ISA_B/C (-opt-mul and -opt-speed).
- MULU.L #2..256,Dn optimized to LSL.L #x,Dn (-opt-mul).
- MVZ.? #x,Dn and MVS.? #x,Dn are optimized to MOVEQ #x,Dn.
- ORI.? #0,<ea> optimized to TST.? <ea>.
- SUB.? #x,<ea> optimized to SUBQ.? #x,<ea>, when x is between 1 and 8.
- SUB.? #x,<ea> optimized to ADDQ.? #x,<ea>, when x is between -1 and -8.
- SUBA.? #x,An optimized to LEA (-x,An),An, when x is between -32767 and 32768.

13.6 Known Problems

Some known problems of this module at the moment:

- In some rare cases, mainly by stupid input sources, the optimizer might oscillate forever between two states. When this happens, assembly will be terminated automatically after some time.

13.7 Error Messages

This module has the following error messages:

- 2001: instruction not supported on selected architecture
- 2002: illegal addressing mode
- 2003: invalid register list
- 2004: missing) in register indirect addressing mode
- 2005: address register required
- 2006: bad size extension
- 2007: displacement at bad position
- 2008: base or index register expected
- 2009: missing] in memory indirect addressing mode
- 2010: no extension allowed here
- 2011: illegal scale factor
- 2012: can't scale PC register
- 2013: index register expected
- 2014: too many] in memory indirect addressing mode
- 2015: missing outer displacement
- 2016: %c expected
- 2017: can't use PC register as index
- 2019: data register required
- 2020: illegal bitfield width/offset
- 2021: constant integer expression required
- 2022: value from -64 to 63 required for k-factor
- 2023: need 32 bits to reference a program label

- 2024: option expected
- 2025: absolute value expected
- 2026: operand value out of range: %ld (valid: %ld..%ld)
- 2027: label in operand required
- 2028: using signed operand as unsigned: %ld (valid: %ld..%ld), %ld to fix
- 2029: branch destination out of range
- 2030: displacement out of range
- 2031: absolute displacement expected
- 2032: unknown option %c%c ignored
- 2033: absolute short address out of range
- 2034: 8-bit branch with zero displacement was converted to 16-bit
- 2035: illegal opcode extension
- 2036: extension for unsized instruction ignored
- 2037: immediate operand out of range
- 2038: immediate operand has illegal type or size
- 2039: data objects with %d bits size are not supported
- 2040: data out of range
- 2041: data has illegal type
- 2042: illegal combination of ColdFire addressing modes
- 2043: FP register required
- 2044: unknown cpu type
- 2045: register expected
- 2046: link.w changed to link.l
- 2047: branch out of range changed to jmp
- 2048: lea-displacement out of range, changed into move/add
- 2049: translated (A%d) into (0,A%d) for movep
- 2050: operand optimized: %s
- 2051: operand translated: %s
- 2051: instruction optimized: %s
- 2053: instruction translated: %s
- 2054: branch optimized into: b<cc>.%c
- 2055: branch translated into: b<cc>.%c
- 2056: basereg A%d already in use
- 2057: basereg A%d is already free
- 2058: short-branch to following instruction turned into a nop
- 2059: not a valid small data register
- 2060: small data mode is not enabled
- 2061: division by zero

14 PowerPC cpu module

This chapter documents the Backend for the PowerPC microprocessor family.

14.1 Legal

This module is written in 2002-2006,2008,2011 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

14.2 Additional options for this module

This module provides the following additional options:

- `'-big'` Select big-endian mode.
- `'-little'` Select little-endian mode.
- `'-m601'` Generate code for the 601.
- `'-many'` Allow any PPC instruction.
- `'-mavec, -maltivec'`
 Generate code for the AltiVec unit.
- `'-mcom'` Allow only common PPC instructions.
- `'-mppc32, -mppc -m403, -m405, -m603, -m604, -m750, -m860'`
 Generate code for the 32-bit PowerPC family.
- `'-mppc64, -m620'`
 Generate code for the 64-bit PowerPC family.
- `'-mpwr'` Generate code for the POWER family.
- `'-mpwrx, -mpwr2'`
 Generate code for the POWER2 family.
- `'-no-regnames'`
 Don't predefine any register-name symbols.
- `'-opt-branch'`
 Enables 'optimization' of 16-bit branches into "B<!cc> \$+8 ; B label" sequences
 when necessary.
- `'-sd2reg=<n>'`
 Sets the 2nd small data base register to Rn.
- `'-sereg=<n>'`
 Sets small data base register to Rn.

14.3 General

This backend accepts PowerPC instructions as described in the instruction set manuals from IBM and Motorola (e.g. the PowerPC Programming Environments).

The full instruction set of the following families is supported: POWER, POWER2, 40x, 60x, 620, 750, 74xx (including AltiVec), 860.

The target address type is 32bit.

Default alignment for sections and instructions is 4 bytes. Data is aligned to its natural alignment by default.

14.4 Extensions

This backend provides the following specific extensions:

- When not disabled by the option `-no-regnames`, the registers r0 - r31, f0 - f31, v0 - v31, cr0 - cr7, vrsave, sp, rtoc, fp, fpscr, xer, lr, ctr, and the symbols lt, gt, so and un will be predefined on startup and may be referenced by the program.

This backend extends the selected syntax module by the following directives:

```
.sdreg <n>
    Sets the small data base register to Rn.

.sd2reg <n>
    Sets the 2nd small data base register to Rn.
```

14.5 Optimizations

This backend performs the following optimizations:

- 16-bit branches, where the destination is out of range, are translated into B<!cc> \$+8 and a 26-bit unconditional branch.

14.6 Known Problems

Some known problems of this module at the moment:

- No real differentiation between 403, 750, 860 instructions at the moment.
- New instructions from modern CPUs are still missing.

14.7 Error Messages

This module has the following error messages:

- 2002: instruction not supported on selected architecture
- 2003: constant integer expression required
- 2004: trailing garbage in operand
- 2005: illegal operand type
- 2006: missing closing parenthesis in load/store addressing mode
- 2007: relocation does not allow hi/lo modifier
- 2008: multiple relocation attributes
- 2009: multiple hi/lo modifiers

- 2010: data size %d not supported
- 2012: relocation attribute not supported by operand
- 2013: operand out of range: %ld (allowed: %ld to %ld)
- 2014: not a valid register (0-31)
- 2015: missing base register in load/store addressing mode
- 2016: missing mandatory operand
- 2017: ignoring fake operand

15 c16x/st10 cpu module

This chapter documents the Backend for the c16x/st10 microcontroller family.

Note that this module is not yet fully completed!

15.1 Legal

This module is copyright in 2002-2004 by Volker Barthelmann.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

15.2 Additional options for this module

This module provides the following additional options:

‘-no-translations’

Do not translate between jump instructions. If the offset of a `jmp` instruction is too large, it will not be translated to `jmps` but an error will be emitted.

Also, `jmpa` will not be optimized to `jmp`.

The pseudo-instruction `jmp` will still be translated.

‘-jmpa’ A `jmp` or `jmp` instruction that is translated due to its offset being larger than 8 bits will be translated to a `jmpa` rather than a `jmps`, if possible.

15.3 General

This backend accepts c16x/st10 instructions as described in the Infineon instruction set manuals.

The target address type is 32bit.

Default alignment for sections and instructions is 2 bytes.

15.4 Extensions

This backend provides the following specific extensions:

- There is a pseudo instruction `jmp` that will be translated either to a `jmp` or `jmpa` instruction, depending on the offset.
- The `sfr` pseudo opcode can be used to declare special function registers. It has two, three or four arguments. The first argument is the identifier to be declared as special function register. The second argument is either the 16bit `sfr` address or its 8bit base address (0xfe for normal `sfrs` and 0xf0 for extended special function registers). In the latter case, the third argument is the 8bit `sfr` number. If another argument is given, it specifies the bit-number in the `sfr` (i.e. the declaration declares a single bit).

Example:

```
.sfr    zeros,0xfe,0x8e
```

- SEG and SOF can be used to obtain the segment or segment offset of a full address. Example:

```
mov r3,#SEG farfunc
```

15.5 Optimizations

This backend performs the following optimizations:

- `jmp` is translated to `jmp r`, if possible. Also, if ‘`-no-translations`’ was not specified, `jmp r` and `jmp a` are translated.
- Relative jump instructions with an offset that does not fit into 8 bits are translated to a `jmps` instruction or an inverted jump around a `jmps` instruction.
- For instruction that have two forms `gpr,#IMM3/4` and `reg,#IMM16` the smaller form is used, if possible.

15.6 Known Problems

Some known problems of this module at the moment:

- Lots...

15.7 Error Messages

This module has the following error messages:

- 2001: illegal operand
- 2002: word register expected
- 2004: value does not find in %d bits
- 2005: data size not supported
- 2006: illegal use of SOF
- 2007: illegal use of SEG
- 2008: illegal use of DPP prefix

16 6502 cpu module

This chapter documents the backend for the MOS/Rockwell 6502 microprocessor family.

16.1 Legal

This module is copyright in 2002,2006,2008-2011 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

16.2 Additional options for this module

This module provides the following additional options:

- ‘-dtv’ Recognize the three additional C64-DTV instructions.
- ‘-illegal’ Allow ‘illegal’ 6502 instructions to be recognized.
- ‘-opt-branch’ Enables ‘optimization’ of B<cc> branches into "B<!cc> *+3 ; JMP label" sequences when necessary.

16.3 General

This backend accepts 6502 family instructions as described in the instruction set reference manuals from MOS and Rockwell, which are valid for the following CPUs: 6502, 65C02, 65CE02, 65C102, 65C112, 6503, 6504, 6505, 6507, 6508, 6509, 6510, 6511, 65F11, 6512 - 6518, 65C00/21, 65C29, 6570, 6571, 6280, 6702, 740, 7501, 8500, 8502, 65802, 65816.

The target address type is 16 bit.

Instructions consist of one up to three bytes and require no alignment. There is also no alignment requirement for sections and data.

All known mnemonics for illegal instructions are recognized (e.g. `dcm` and `dcp` refer to the same instruction). Some illegal instructions (e.g. `$ab`) are known to show unpredictable behaviour, or do not always work the same on different CPUs.

16.4 Extensions

This backend provides the following specific extensions:

- The parser understands a lo/hi-modifier to select low- or high-byte of a 16-bit word. The character < is used to select the low-byte and > for the high-byte. It has to be the first character before an expression.
- When applying the operation /256, %256 or &256 on a label, an appropriate lo/hi-byte relocation will automatically be generated.

16.5 Optimizations

This backend performs the following operand optimizations:

- Branches, where the destination is out of range, are translated into `B<!cc> *+3` and an absolute `JMP` instruction.

16.6 Known Problems

Some known problems of this module at the moment:

- None.

16.7 Error Messages

This module has the following error messages:

- 2001: instruction not supported on selected architecture
- 2002: trailing garbage in operand
- 2003: missing closing parenthesis in addressing mode
- 2004: data size `%d` not supported
- 2005: relocation does not allow hi/lo modifier
- 2006: operand doesn't fit into 8-bits
- 2007: branch destination out of range

17 ARM cpu module

This chapter documents the backend for the Advanced RISC Machine (ARM) microprocessor family.

17.1 Legal

This module is copyright in 2004,2006 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

17.2 Additional options for this module

This module provides the following additional options:

- `'-a2'` Generate code compatible with ARM V2 architecture.
- `'-a3'` Generate code compatible with ARM V3 architecture.
- `'-a3m'` Generate code compatible with ARM V3m architecture.
- `'-a4'` Generate code compatible with ARM V4 architecture.
- `'-a4t'` Generate code compatible with ARM V4t architecture.
- `'-big'` Output big-endian code and data.
- `'-little'` Output little-endian code and data (default).
- `'-m2'` Generate code for the ARM2 CPU.
- `'-m250'` Generate code for the ARM250 CPU.
- `'-m3'` Generate code for the ARM3 CPU.
- `'-m6'` Generate code for the ARM6 CPU.
- `'-m600'` Generate code for the ARM600 CPU.
- `'-m610'` Generate code for the ARM610 CPU.
- `'-m7'` Generate code for the ARM7 CPU.
- `'-m710'` Generate code for the ARM710 CPU.
- `'-m7500'` Generate code for the ARM7500 CPU.
- `'-m7d'` Generate code for the ARM7d CPU.
- `'-m7di'` Generate code for the ARM7di CPU.
- `'-m7dm'` Generate code for the ARM7dm CPU.
- `'-m7dmi'` Generate code for the ARM7dmi CPU.
- `'-m7tdmi'` Generate code for the ARM7tdmi CPU.

<code>'-m8'</code>	Generate code for the ARM8 CPU.
<code>'-m810'</code>	Generate code for the ARM810 CPU.
<code>'-m9'</code>	Generate code for the ARM9 CPU.
<code>'-m9'</code>	Generate code for the ARM9 CPU.
<code>'-m920'</code>	Generate code for the ARM920 CPU.
<code>'-m920t'</code>	Generate code for the ARM920t CPU.
<code>'-m9tdmi'</code>	Generate code for the ARM9tdmi CPU.
<code>'-msa1'</code>	Generate code for the SA1 CPU.
<code>'-mstrongarm'</code>	Generate code for the STRONGARM CPU.
<code>'-mstrongarm110'</code>	Generate code for the STRONGARM110 CPU.
<code>'-mstrongarm1100'</code>	Generate code for the STRONGARM1100 CPU.
<code>'-opt-adr'</code>	The <code>ADR</code> directive will be automatically converted into <code>ADRL</code> if required (which inserts an additional <code>ADD/SUB</code> to calculate an address).
<code>'-opt-ldrpc'</code>	The maximum range in which PC-relative symbols can be accessed through <code>LDR</code> and <code>STR</code> is extended from $\pm 4\text{KB}$ to $\pm 1\text{MB}$ (or ± 256 Bytes to ± 65536 Bytes when accessing half-words). This is done by automatically inserting an additional <code>ADD</code> or <code>SUB</code> instruction before the <code>LDR/STR</code> .
<code>'-thumb'</code>	Start assembling in Thumb mode.

17.3 General

This backend accepts ARM instructions as described in various ARM CPU data sheets. Additionally some architectures support a second, more dense, instruction set, called THUMB. There are special directives to switch between those two instruction sets.

The target address type is 32bit.

Default alignment for instructions is 4 bytes for ARM and 2 bytes for THUMB. Sections will be aligned to 4 bytes by default. Data is aligned to its natural alignment by default.

17.4 Extensions

This backend extends the selected syntax module by the following directives:

<code>.arm</code>	Generate 32-bit ARM code.
<code>.thumb</code>	Generate 16-bit THUMB code.

17.5 Optimizations

This backend performs the following optimizations and translations for the ARM instruction set:

- LDR/STR Rd,symbol, with a distance between symbol and PC larger than 4KB, is translated to ADD/SUB Rd,PC,#offset&0xff000 + LDR/STR Rd,[Rd,#offset&0xff], when allowed by the option `-opt-ldrpc`.
- ADR Rd,symbol is translated to ADD/SUB Rd,PC,#rotated_offset8.
- ADRL Rd,symbol is translated to ADD/SUB Rd,PC,#hi_rotated8 + ADD/SUB Rd,Rd,#lo_rotated8. ADR will be automatically treated as ADRL when required and when allowed by the option `-opt-adr`.
- The immediate operand of ALU-instructions will be translated into the appropriate 8-bit-rotated value. When rotation alone doesn't succeed the backend will try it with inverted and negated values (inverting/negating the ALU-instruction too).

For the THUMB instruction set the following optimizations and translations are done:

- A conditional branch with a branch-destination being out of range is translated into `B<!cc> .+4 + B label`.
- The BL instruction is translated into two sub-instructions combining the high- and low 22 bit of the branch displacement.

17.6 Known Problems

Some known problems of this module at the moment:

- Only instruction sets up to ARM architecture V4t are supported.

17.7 Error Messages

This module has the following error messages:

- 2001: instruction not supported on selected architecture
- 2002: trailing garbage in operand
- 2003: label from current section required
- 2004: branch offset (%ld) is out of range
- 2005: PC-relative load/store (offset %ld) out of range
- 2006: cannot make rotated immediate from PC-relative offset (0x%lx)
- 2007: constant integer expression required
- 2008: constant (0x%lx) not suitable for 8-bit rotated immediate
- 2009: branch to an unaligned address (offset %ld)
- 2010: not a valid ARM register
- 2011: PC (r15) not allowed in this mode
- 2012: PC (r15) not allowed for offset register Rm
- 2013: PC (r15) not allowed with write-back
- 2014: register r%ld was used multiple times
- 2015: illegal immediate shift count (%ld)

- 2016: not a valid shift register
- 2017: 24-bit unsigned immediate expected
- 2018: data size %d not supported
- 2019: illegal addressing mode: %s
- 2020: signed/halfword ldr/str doesn't support shifts
- 2021: %d-bit immediate offset out of range (%ld)
- 2022: post-indexed addressing mode expected
- 2023: operation not allowed on external symbols
- 2024: ldc/stc offset has to be a multiple of 4
- 2025: illegal coprocessor operation mode or type: %ld\n
- 2026: %d-bit unsigned immediate offset out of range (%ld)
- 2027: offset has to be a multiple of %d
- 2028: instruction at unaligned address

18 80x86 cpu module

This chapter documents the Backend for the 80x86 microprocessor family.

18.1 Legal

This module is written in 2005-2006,2011 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

18.2 Additional options for this module

This module provides the following additional options:

- `'-cpudebug=<n>'`
Enables debugging output.
- `'-m8086'` Generate code for the 8086 CPU.
- `'-mi186'` Generate code for the 80186 CPU.
- `'-mi286'` Generate code for the 80286 CPU.
- `'-mi386'` Generate code for the 80386 CPU.
- `'-mi486'` Generate code for the 80486 CPU.
- `'-mi586'` Generate code for the Pentium.
- `'-mi686'` Generate code for the PentiumPro.
- `'-mpentium'`
Generate code for the Pentium.
- `'-mpentiumpro'`
Generate code for the PentiumPro.
- `'-mk6'` Generate code for the AMD K6.
- `'-mathlon'`
Generate code for the AMD Athlon.
- `'-msledgehammer'`
Generate code for the Sledgehammer CPU.
- `'-m64'` Generate code for 64-bit architectures (x86_64).

18.3 General

This backend accepts 80x86 instructions as described in the Intel Architecture Software Developer's Manual.

The target address type is 32bit.

Default alignment for sections is 4 bytes. Instructions do not need any alignment. Data is aligned to its natural alignment by default.

The backend uses MIT-syntax! This means the left operands are always the source and the right operand is the destination. Also register names have to be prefixed by a '%'. Operation size is indicated by a 'b', 'w', 'l', etc. suffix behind the mnemonic.

18.4 Extensions

Predefined register symbols in this backend:

- 8-bit registers: `al cl dl bl ah ch dh bh axl cxl dxl spl bpl sil dil r8b r9b r10b r11b r12b r13b r14b r15b`
- 16-bit registers: `ax cx dx bx sp bp si di r8w r9w r10w r11w r12w r13w r14w r15w`
- 32-bit registers: `eax ecx edx ebx esp ebp esi edi r8d r9d r10d r11d r12d r13d r14d r15d`
- 64-bit registers: `rax rcx rdx rbx rsp ebp rsi rdi r8 r9 r10 r11 r12 r13 r14 r15`
- segment registers: `es cs ss ds fs gs`
- control registers: `cr0 cr1 cr2 cr3 cr4 cr5 cr6 cr7 cr8 cr9 cr10 cr11 cr12 cr13 cr14 cr15`
- debug registers: `dr0 dr1 dr2 dr3 dr4 dr5 dr6 dr7 dr8 dr9 dr10 dr11 dr12 dr13 dr14 dr15`
- test registers: `tr0 tr1 tr2 tr3 tr4 tr5 tr6 tr7`
- MMX and SIMD registers: `mm0 mm1 mm2 mm3 mm4 mm5 mm6 mm7 xmm0 xmm1 xmm2 xmm3 xmm4 xmm5 xmm6 xmm7 xmm8 xmm9 xmm10 xmm11 xmm12 xmm13 xmm14 xmm15`
- FPU registers: `st st(0) st(1) st(2) st(3) st(4) st(5) st(6) st(7)`

This backend extends the selected syntax module by the following directives:

- `.code16` Sets the assembler into 16-bit addressing mode.
- `.code32` Sets the assembler into 32-bit addressing mode, which is the default.
- `.code64` Sets the assembler into 64-bit addressing mode.

18.5 Optimizations

This backend performs the following optimizations:

- Immediate operands are optimized to the smallest size which can still represent the absolute value.
- Displacement operands are optimized to the smallest size which can still represent the absolute value.
- Jump instructions are optimized to 8-bit displacements, when possible.

18.6 Known Problems

Some known problems of this module at the moment:

- 64-bit operations are incomplete and experimental.

18.7 Error Messages

This module has the following error messages:

- 2001: instruction not supported on selected architecture
- 2002: trailing garbage in operand
- 2003: same type of prefix used twice
- 2004: immediate operand illegal with absolute jump
- 2005: base register expected
- 2006: scale factor without index register
- 2007: missing ')' in baseindex addressing mode
- 2008: redundant %s prefix ignored
- 2009: unknown register specified
- 2010: using register %%%s instead of %%%s due to '%c' suffix
- 2011: %%%s not allowed with '%c' suffix
- 2012: illegal suffix '%c'
- 2013: instruction has no suffix and no register operands - size is unknown
- 2015: memory operand expected
- 2016: you cannot pop %%%s
- 2017: translating to %s %%%s,%%s
- 2018: translating to %s %%%s
- 2019: absolute scale factor required
- 2020: illegal scale factor (valid: 1,2,4,8)
- 2021: data objects with %d bits size are not supported
- 2022: need at least %d bits for a relocatable symbol
- 2023: pc-relative jump destination out of range (%lld)
- 2024: instruction doesn't support these operand sizes
- 2025: cannot determine immediate operand size without a suffix
- 2026: displacement doesn't fit into %d bits

19 z80 cpu module

This chapter documents the backend for the 8080/z80/gbz80/64180/RCMx000 microprocessor family.

19.1 Legal

This module is copyright in 2009 by Dominic Morris

19.2 Additional options for this module

This module provides the following additional options:

- '-8080' Turns on 8080 compatibility mode. Any use of z80 (or higher) opcodes will result in an error being generated.
- '-gbz80' Turns on gbz80 compatibility mode. Any use of non-supported opcodes will result in an error being generated.
- '-hd64180' Turns on 64180 mode supporting additional 64180 opcodes.
- '-rcm2000'
- '-rcm3000'
- '-rcm4000' Turns on Rabbit compatibility mode, generating the correct codes for moved opcodes and supporting the additional Rabbit instructions. In this mode, 8 bit access to the 16 bit index registers is not permitted.
- '-rcmemu' Turns on emulation of some instructions which aren't available on the Rabbit processors.
- '-swapixiy' Swaps the usage of ix and iy registers. This is useful for compiling generic code that uses an index register that is reserved on the target machine.
- '-z80asm' Switches on z80asm mode. This translates ASMPc to \$ and accepts some pseudo opcodes that z80asm supports. Most emulation of z80asm directives is provided by the oldsyntax syntax module.

19.3 General

This backend accepts z80 family instructions in standard Zilog syntax. Rabbit opcodes are accepted as defined in the publically available reference material from Rabbit Semiconductor, with the exception that the `ljp` and `lcall` opcodes need to be supplied with a 24 bit number rather than an 8 bit `xpc` and a 16 bit address.

The target address type is 16 bit.

Instructions consist of one up to six bytes and require no alignment. There is also no alignment requirement for sections and data.

19.4 Extensions

This backend provides the following specific extensions:

- Certain Rabbit opcodes can be prefixed by the `altd` and/or the `ioi/ioe` modifier. For details of which instructions these are valid for please see the documentation from Rabbit.
- The parser understands a `lo/hi`-modifier to select low- or high-byte of a 16-bit word. The character `<` is used to select the low-byte and `>` for the high-byte. It has to be the first character before an expression.
- When applying the operation `/256`, `%256` or `&256` on a label, an appropriate `lo/hi`-byte relocation will automatically be generated.

19.5 Optimisations

This backend supports the emulation of certain z80 instructions on the Rabbit/gbz80 processor. These instructions are `rld`, `rrd`, `cpi`, `cpir`, `cpd` and `cpdr`. The link stage should provide routines with the opcode name prefixed with `rcmx_` (eg `rcmx_rld`) which implements the same functionality. Example implementations are available within the z88dk CVS tree.

Additionally, for the Rabbit targets the missing call `cc`, opcodes will be emulated.

19.6 Known Problems

Some known problems of this module at the moment:

- Not all RCM4000 opcodes are supported (`llcall`, `lljp` are not available).

19.7 Error Messages

This module has the following error messages:

- 2001: index offset out of bounds (%d)
- 2002: Opcode not supported by %s (%s)
- 2003: Index registers not available on 8080
- 2004: out of range for 8 bit expression (%d)
- 2005: invalid bit number (%d) should be in range 0..7
- 2006: rst value out of range (%d/0x%02x)
- 2007: %s value out of range (%d)
- 2008: index offset should be a constant
- 2009: invalid branch type for jr
- 2010: Rabbit target doesn't support rst %d
- 2011: Rabbit target doesn't support 8 bit index registers
- 2012: z180 target doesn't support 8 bit index registers
- 2013: invalid branch type for jre
- 2014: Opcode not supported by %s (%s) but it can be emulated (-rcmemu)
- 2015: %s specifier is only valid for Rabbit processors

- 2016: Only one of ioi and ioe can be specified at a time
- 2017: %s specifier is not valid for the opcode %s
- 2018: %s specifier redundant for the opcode %s
- 2019: %s specifier has no effect on the opcode %s
- 2020: Operand value must evaluate to a constant for opcode %s
- 2021: Unhandled operand type wanted 0x%x got 0x%x
- 2022: Missed matched index registers on %s
- 2023: Only out (c),0 is supported for the opcode %s
- 2024: Operations between different index registers are forbidden
- 2025: Operations between ix/iy/hl are forbidden
- 2026: Double indirection forbidden

20 6800 cpu module

This chapter documents the backend for the Motorola 6800 microprocessor family.

20.1 Legal

This module is copyright in 2013-2014 by Esben Norby and Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

20.2 Additional options for this module

This module provides the following additional options:

`'-m6800'` Generate code for the 6800 CPU (default setting).

`'-m68hc11'`
 Generate code for the 68HC11 CPU.

20.3 General

This backend accepts 6800 family instructions for the following CPUs: 6800, 6801, 6802, 6803, 6805, 68HC05, 6808, 68HC08, 68HC11.

The target address type is 16 bit.

Instructions consist of one up to five bytes and require no alignment. There is also no alignment requirement for sections and data.

20.4 Extensions

This backend provides the following specific extensions:

- When an instruction supports direct and extended addressing mode the < character can be used to force direct mode and the > character forces extended mode. Otherwise the assembler selects the best mode automatically, which defaults to extended mode for external symbols.
- When applying the operation /256, %256 or &256 on a label, an appropriate lo/hi-byte relocation will automatically be generated.

20.5 Optimizations

None.

20.6 Known Problems

Some known problems of this module at the moment:

- None?

20.7 Error Messages

This module has the following error messages:

- 2001: data size %d not supported
- 2002: operand doesn't fit into 8-bits
- 2003: branch destination out of range

21 Jaguar RISC cpu module

This chapter documents the backend for the Atari Jaguar GPU/DSP RISC processor.

21.1 Legal

This module is copyright in 2014 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

Distributing modified versions and commercial usage needs my written consent.

Certain modules may fall under additional copyrights.

21.2 Additional options for this module

This module provides the following additional options:

- '-big' Output big-endian code and data (default).
- '-little' Output little-endian code and data.
- '-many' Generate code for GPU or DSP RISC. All instructions are accepted (default).
- '-mdsp'
- '-mjerry' Generate code for the DSP RISC (part of Jerry).
- '-mgpu'
- '-mtom' Generate code for the GPU RISC (part of Tom).

21.3 General

This backend accepts RISC instructions for the GPU or DSP in Atari's Jaguar custom chip set according to the "Jaguar Technical Reference Manual for Tom & Jerry", Revision 8. Documentation bugs were fixed by using various sources on the net.

The target address type is 64bit.

Default alignment for instructions is 2 bytes. Data is aligned to its natural alignment by default.

21.4 Optimizations

This backend performs the following optimizations and translations for the GPU/DSP RISC instruction set:

- `load (Rn+0),Rm` is optimized to `load (Rn),Rm`.
- `store Rn,(Rm+0)` is optimized to `store Rn,(Rm)`.

21.5 Known Problems

Some known problems of this module at the moment:

- Encoding of MOVEI instruction in little-endian mode is unknown.
- The developer has to provide the necessary NOP instructions after jumps, or OR instructions to work around hardware bugs, himself.

21.6 Error Messages

This module has the following error messages:

- 2001: data size %d not supported
- 2002: value from %ld to %ld required

22 Interface

22.1 Introduction

This chapter is under construction!

This chapter describes some of the internals of `vasm` and tries to explain what has to be done to write a cpu module, a syntax module or an output module for `vasm`. However if someone wants to write one, I suggest to contact me first, so that it can be integrated into the source tree.

Note that this documentation may mention explicit values when introducing symbolic constants. This is due to copying and pasting from the source code. These values may not be up to date and in some cases can be overridden. Therefore do never use the absolute values but rather the symbolic representations.

22.2 Building vasm

This section deals with the steps necessary to build the typical `vasm` executable from the sources.

22.2.1 Directory Structure

The `vasm`-directory contains the following important files and directories:

`'vasm/'` The main directory containing the assembler sources.

`'vasm/Makefile'`
 The Makefile used to build `vasm`.

`'vasm/syntax/<syntax-module>/'`
 Directories for the syntax modules.

`'vasm/cpus/<cpu-module>/'`
 Directories for the cpu modules.

`'vasm/obj/'`
 Directory the object modules will be stored in.

All compiling is done from the main directory and the executables will be placed there as well. The main assembler for a combination of `<cpu>` and `<syntax>` will be called `vasm<cpu>_<syntax>`. All output modules are usually integrated in every executable and can be selected at runtime.

22.2.2 Adapting the Makefile

Before building anything you have to insert correct values for your compiler and operating system in the `'Makefile'`.

TARGET Here you may define an extension which is appended to the executable's name. Useful, if you build various targets in the same directory.

TARGETEXTENSION
 Defines the file name extension for executable files. Not needed for most operating systems. For Windows it would be `' .exe'`.

- CC** Here you have to insert a command that invokes an ANSI C compiler you want to use to build vasm. It must support the '-I' option the same like e.g. `vc` or `gcc`.
- COPTS** Here you will usually define an option like '-c' to instruct the compiler to generate an object file. Additional options, like the optimization level, should also be inserted here as well. When the host operating system is different from a Unix (MacOSX and MiNT are Unix), you have to define one of the following preprocessor macros:
- DAMIGA AmigaOS (M68k or PPC), MorphOS, AROS.
 - DATARI Atari TOS.
 - DMSDOS CP/M, MS-DOS, Windows.
- CCOUT** Here you define the option which is used to specify the name of an output file, which is usually '-o'.
- LD** Here you insert a command which starts the linker. This may be the the same as under **CC**.
- LDFLAGS** Here you have to add options which are necessary for linking. E.g. some compilers need special libraries for floating-point.
- LDOUT** Here you define the option which is used by the linker to specify the output file name.
- RM** Specify a command to delete a file, e.g. `rm -f`.

An example for the Amiga using `vbcc` would be:

```
TARGET = _os3
TARGETEXTENSION =
CC = vc +aos68k
CCOUT = -o
COPTS = -c -c99 -cpu=68020 -DAMIGA -O1
LD = $(CC)
LDOUT = $(CCOUT)
LDFLAGS = -lmieee
RM = delete force quiet
```

An example for a typical Unix-installation would be:

```
TARGET =
TARGETEXTENSION =
CC = gcc
CCOUT = -o
COPTS = -c -O2
LD = $(CC)
LDOUT = $(CCOUT)
LDFLAGS = -lm
RM = rm -f
```

Open/Net/Free/Any BSD i386 systems will probably require the following an additional '-D_ANSI_SOURCE' in **COPTS**.

22.2.3 Building vasm

Note to users of Open/Free/Any BSD i386 systems: You will probably have to use GNU make instead of BSD make, i.e. in the following examples replace "make" with "gmake".

Type:

```
make CPU=<cpu> SYNTAX=<syntax>
```

For example:

```
make CPU=ppc SYNTAX=std
```

The following CPU modules can be selected:

- CPU=6502
- CPU=arm
- CPU=c16x
- CPU=jagrisc
- CPU=m68k
- CPU=ppc
- CPU=test
- CPU=vidcore
- CPU=x86
- CPU=z80

The following syntax modules can be selected:

- SYNTAX=std
- SYNTAX=mot
- SYNTAX=oldstyle
- SYNTAX=test

For Windows and various Amiga targets there are already Makefiles included, which you may either copy on top of the default 'Makefile', or call it explicitly with make's '-f' option:

```
make -f Makefile.OS4 CPU=ppc SYNTAX=std
```

22.3 General data structures

This section describes the fundamental data structures used in vasm which are usually necessary to understand for writing any kind of module (cpu, syntax or output). More detailed information is given in the respective sections on writing specific modules where necessary.

22.3.1 Source

A source structure represents a source text module, which can be either the main source text, an included file or a macro. There is always a link to the parent source from where the current source context was included or called.

```
struct source *parent;
```

Pointer to the parent source context. Assembly continues there when the current source context ends.

`int parent_line;`
Line number in the parent source context, from where we were called. This information is needed, because line numbers are only reliable during parsing and later from the atoms. But an include directive doesn't create an atom.

`char *name;`
File name of the main source or include file, or macro name.

`char *text;`
Pointer to the source text start.

`size_t size;`
Size of the source text to assemble in bytes.

`unsigned long repeat;`
Number of repetitions of this source text. Usually this is 1, but for text blocks between a `rept` and `endr` directive it allows any number of repetitions, which is decremented everytime the end of this source text block is reached.

`int cond_level;`
Current level of conditional nesting while calling this macro. The level is provided by the syntax module through `execute_macro()`. The syntax module may use this information to restore the last valid level when exiting a macro in the middle.

`int num_params;`
Number of macro parameters passed at the invocation point from the parent source. For normal source files this entry will be -1. For macros 0 (no parameters) or higher.

`char *param[MAXMACPARAMS];`
Pointer to the macro parameters. Parameter 0 is usually reserved for a special purpose, like the mnemonic's first qualifier.

`int param_len[MAXMACPARAMS];`
Number of characters per macro parameter.

`unsigned long id;`
Every source has its unique id. Useful for macros supporting the special `\@` parameter.

`char *srcptr;`
The current source text pointer, pointing to the beginning of the next line to assemble.

`int line;` Line number in the current source context. After parsing the line number of the current atom is stored here.

`char *linebuf;`
A `MAXLINELENGTH` buffer for the current line being assembled in this source text. A child-source, like a macro, can refer to arguments from this buffer, so every source has got its own. When returning to the parent source, the `linebuf` is deallocated to save memory.

22.3.2 Sections

One of the top level structures is a linked list of sections describing continuous blocks of memory. A section is specified by an object of type `section` with the following members that can be accessed by the modules:

```
struct section *next;
```

A pointer to the next section in the list.

```
char *name;
```

The name of the section.

```
char *attr;
```

A string describing the section flags in ELF notation (see, for example, documentation of the `.section` directive of the standard syntax module).

```
atom *first;
```

```
atom *last;
```

Pointers to the first and last atom of the section. See following sections for information on atoms.

```
taddr align;
```

Alignment of the section in bytes.

```
uint32_t flags;
```

Flags of the section. Currently available flags are:

HAS_SYMBOLS

At least one symbol is defined in this section.

RESOLVE_WARN

The current atom changed its size multiple times, so `atom_size()` is now called with this flag set in its section to make the back-end (e.g. `instruction_size()`) aware of it and do less aggressive optimizations.

UNALLOCATED

Section is unallocated, which means it doesn't use any memory space in the output file. Such a section will be removed before creating the output file and all its labels converted into absolute expression symbols. Used for "offset" sections. Refer to `switch_offset_section()`.

LABELS_ARE_LOCAL

As long as this flag is set new labels in a section are defined as local labels, with the section name as global parent label.

ABSOLUTE Section is loaded at an absolute address in memory.

```
taddr org;
```

Start address of a section. Usually zero.

```
taddr pc;
```

Current address in this section. Can be used while traversing through the section. Has to be updated by a module using it. Is set to `org` at the beginning.

```
uint32_t idx;
```

A member usable by the output module for private purposes.

22.3.3 Symbols

Symbols are represented by a linked list of type `symbol` with the following members that can be accessed by the modules:

`int type;` Type of the symbol. Available are:

```
#define LABSYM 1
    The symbol is a label defined at a specific location.

#define IMPORT 2
    The symbol is imported from another file.

#define EXPRESSION 3
    The symbol is defined using an expression.
```

`uint32_t flags;`

Flags of this symbol. Available are:

```
#define TYPE_UNKNOWN 0
    The symbol has no type information.

#define TYPE_OBJECT 1
    The symbol defines an object.

#define TYPE_FUNCTION 2
    The symbol defines a function.

#define TYPE_SECTION 3
    The symbol defines a section.

#define TYPE_FILE 4
    The symbol defines a file.

#define EXPORT (1<<3)
    The symbol is exported to other files.

#define INEVAL (1<<4)
    Used internally.

#define COMMON (1<<5)
    The symbol is a common symbol.

#define WEAK (1<<6)
    The symbol is weak, which means the linker may overwrite it with
    any global definition of the same name. Weak symbols may also
    stay undefined, in which case the linker would assign them a value
    of zero.

#define VASMINTERN (1<<7)
    Vasm-internal symbol, which is usually not exported into an output
    file.

#define PROTECTED (1<<8)
    Used internally to protect the current-PC symbol from deletion.
```

```
#define RSRVD_S (1L<<24)
```

The range from bit 24 to 27 (counted from the LSB) is reserved for use by the syntax module.

```
#define RSRVD_O (1L<<28)
```

The range from bit 28 to 31 (counted from the LSB) is reserved for use by the output module.

The type-flags can be extracted using the `TYPE()` macro which expects a pointer to a symbol as argument.

```
char *name;
```

The name of the symbol.

```
expr *expr;
```

The expression in case of `EXPRESSION` symbols.

```
expr *size;
```

The size of the symbol, if specified.

```
section *sec;
```

The section a `LABSYM` symbol is defined in.

```
taddr pc;
```

The address of a `LABSYM` symbol.

```
taddr align;
```

The alignment of the symbol in bytes.

```
uint32_t idx;
```

A member usable by the output module for private purposes.

22.3.4 Register symbols

Optional register symbols are available when the backend defines `HAVE_REGSYMS` in ‘`cpu.h`’ together with the hash table size. Example:

```
#define HAVE_REGSYMS
```

```
#define REGSYMHTSIZE 256
```

A register symbol is defined by an object of type `regsym` with the following members that can be accessed by the modules:

```
char *reg_name;
```

Symbol name.

```
int reg_type;
```

Optional type of register.

```
unsigned int reg_flags;
```

Optional register symbol flags.

```
unsigned int reg_num;
```

Register number or value.

Refer to ‘`symbol.h`’ for functions to create and find register symbols.

22.3.5 Atoms

The contents of each section are a linked list built out of non-separable atoms. The general structure of an atom is:

```
typedef struct atom {
    struct atom *next;
    int type;
    taddr align;
    taddr lastsize;
    unsigned changes;
    source *src;
    int line;
    listing *list;
    union {
        instruction *inst;
        dblock *db;
        symbol *label;
        sblock *sb;
        defblock *defb;
        void *opts;
        int srcline;
        char *ptext;
        expr *pexpr;
        expr *roffs;
        taddr *rorg;
        assertion *assert;
    } content;
} atom;
```

The members have the following meaning:

`struct atom *next;`
 Pointer to the following atom (0 if last).

`int type;` The type of the atom. Can be one of

`#define LABEL 1`

A label is defined here.

`#define DATA 2`

Some data bytes of fixed length and constant data are put here.

`#define INSTRUCTION 3`

Generally refers to a machine instruction or pseudo/opcode. These atoms can change length during optimization passes and will be translated to DATA-atoms later.

`#define SPACE 4`

Defines a block of data filled with one value (byte). BSS sections usually contain only such atoms, but they are also sometimes useful as shorter versions of DATA-atoms in other sections.

#define DATADEF 5
 Defines data of fixed size which can contain cpu specific operands and expressions. Will be translated to **DATA**-atoms later.

#define LINE 6
 A source text line number (usually from a high level language) is bound to the atom's address. Useful for source level debugging in certain ABIs.

#define OPTS 7
 A means to change assembler options at a specific source text line. For example optimization settings, or the cpu type to generate code for. The cpu module has to define **HAVE_CPU_OPTS** and export the required functions if it wants to use this type of atom.

#define PRINTTEXT 8
 A string is printed to stdout during the final assembler pass. A newline is automatically appended.

#define PRINTEXPR 9
 Prints the value of an expression during the final assembler pass to stdout.

#define ROFFS 10
 Set the program counter to an address relative to the section's start address. These atoms will be translated into **SPACE** atoms in the final pass.

#define RORG 11
 Assemble this block under the given base address, while the code is still written into the original memory region.

#define RORGEND 12
 Ends a RORG block and returns to the original addressing.

#define ASSERT 13
 The assertion expression is checked in the final pass and an error message is generated (using the expression string and an optional message out of this atom) when it evaluates to 0.

taddr align;

The alignment of this atom. Address must be dividable by **align**.

taddr lastsize;

The size of this atom in the last resolver pass. When the size has changed in the current pass, the assembler will request another resolver run through the section.

unsigned changes;

Number of changes in the size of this atom since pass number **FASTOPTPHASE**. An increasing number usually indicates a problem in the cpu backend's optimizer and will be flagged by setting **RESOLVE_WARN** in the Section flags, as soon as **changes** exceeds **MAXSIZECHANGES**. So the backend can choose not to optimize this atom as aggressive as before.

```

source *src;
    Pointer to the source text object to which this atom belongs.

int line; The source line number that created this atom.

listing *list;
    Pointer to the listing object to which this atoms belong.

instruction *inst;
    (In union content.) Pointer to an instruction structure in the case of an
    INSTRUCTION-atom. Contains the following elements:

    int code; The cpu specific code of this instruction.

    char *qualifiers[MAX_QUALIFIERS];
        (If MAX_QUALIFIERS!=0.) Pointer to the qualifiers of this instruc-
        tion.

    operand *op[MAX_OPERANDS];
        (If MAX_OPERANDS!=0.) The cpu-specific operands of this instruc-
        tion.

    instruction_ext ext;
        (If the cpu module defines HAVE_INSTRUCTION_EXTENSION.) A cpu-
        module-specific structure. Typically used to store appropriate op-
        codes, allowed addressing modes, supported cpu derivates etc.

dblock *db;
    (In union content.) Pointer to a dblock structure in the case of a DATA-atom.
    Contains the following elements:

    taddr size;
        The number of bytes stored in this atom.

    char *data;
        A pointer to the data.

    rlist *relocs;
        A pointer to relocation information for the data.

symbol *label;
    (In union content.) Pointer to a symbol structure in the case of a LABEL-atom.

sblock *sb;
    (In union content.) Pointer to a sblock structure in the case of a SPACE-atom.
    Contains the following elements:

    taddr space;
        The size of the empty/filled space in bytes.

    expr *space_exp;
        The above size as an expression, which will be evaluated during
        assembly and copied to space in the final pass.

    int size; The size of each space-element and of the fill-pattern in bytes.

```

```

    unsigned char fill[MAXBYTES];
        The fill pattern, up to MAXBYTES bytes.

    expr *fill_exp;
        Optional. Evaluated and copied to fill in the final pass, when not
        null.

    rlist *relocs;
        A pointer to relocation information for the space.

defblock *defb;
    (In union content.) Pointer to a defblock structure in the case of a DATADEF-
    atom. Contains the following elements:

    taddr bitsize;
        The size of the definition in bits.

    operand *op;
        Pointer to a cpu-specific operand structure.

void *opts;
    (In union content.) Points to a cpu module specific options object in the case
    of a OPTS-atom.

int srcline;
    (In union content.) Line number for source level debugging in the case of a
    LINE-atom.

char *ptext;
    (In union content.) A string to print to stdout in case of a PRINTTEXT-atom.

expr *pexpr;
    (In union content.) An expression to evaluate and print to stdout in case of a
    PRINTEXPR-atom.

expr *roffs;
    (In union content.) The expression holds the relative section offset to align to
    in case of a ROFFS-atom.

taddr *rorg;
    (In union content.) Assemble the code under the base address in rorg in case
    of a RORG-atom.

assertion *assert;
    (In union content.) Pointer to an assertion structure in the case of an ASSERT-
    atom. Contains the following elements:

    expr *assert_exp;
        Pointer to an expression which should evaluate to non-zero.

    char *exprstr;
        Pointer to the expression as text (to be used in the output).

    char *msgstr;
        Pointer to the message, which would be printed when assert_exp
        evaluates to zero.

```

22.3.6 Relocations

DATA and SPACE atoms can have a relocation list attached that describes how this data must be modified when linking/relocating. They always refer to the data in this atom only.

There are a number of predefined standard relocations and it is possible to add other cpu-specific relocations. Note however, that it is always preferable to use standard relocations, if possible. Chances that an output module supports a certain relocation are much higher if it is a standard relocation.

A relocation list uses this structure:

```
typedef struct rlist {
    struct rlist *next;
    void *reloc;
    int type;
} rlist;
```

Type identifies the relocation type. All the standard relocations have type numbers between FIRST_STANDARD_RELOC and LAST_STANDARD_RELOC. Consider 'reloc.h' to see which standard relocations are available.

The detailed information can be accessed via the pointer `reloc`. It will point to a structure that depends on the relocation type, so a module must only use it if it knows the relocation type.

All standard relocations point to a type `nreloc` with the following members:

```
int offset;
    The offset (from the start of the DATA-atom in bits.

int size;
    The size of the relocation in bits.

taddr mask;
    A mask value.

taddr addend;
    Value to be added to the symbol value.

symbol *sym;
    The symbol referred by this relocation
```

To describe the meaning of these entries, we will define the steps that shall be performed when performing a relocation:

1. Extract the **size** bits from the data atom, starting with bit number **offset**. An **offset** of zero means starting with the first bit (MSB).
2. Determine the relocation value of the symbol. For a simple absolute relocation, this will be the value of the symbol **sym** plus the **addend**. For other relocation types, more complex calculations will be needed. For example, in a program-counter relative relocation, the value will be obtained by subtracting the address of the data atom (possibly offset by a target specific value) from the value of **sym** plus **addend**.
3. Calculate the bit-wise "and" of the value obtained in the step above and the **mask** value.
4. Normalize, i.e. shift the value above right as many bit positions as there are low order zero bits in **mask**.

5. Add this value to the value extracted in step 1.
6. Insert the low order `size` bits of this value into the data atom starting with bit `offset`.

22.3.7 Errors

Each module can provide a list of possible error messages contained e.g. in `'syntax_errors.h'` or `'cpu_errors.h'`. They are a comma-separated list of a printf-format string and error flags. Allowed flags are `WARNING`, `ERROR`, `FATAL` and `NOLINE`. They can be combined using or (`|`). `NOLINE` has to be set for error messages during initialization or while writing the output, when no source text is available. Errors cause the assembler to return false. `FATAL` causes the assembler to terminate immediately.

The errors can be emitted using the function `syntax_error(int n,...)`, `cpu_error(int n,...)` or `output_error(int n,...)`. The first argument is the number of the error message (starting from zero). Additional arguments must be passed according to the format string of the corresponding error message.

22.4 Syntax modules

A new syntax module must have its own subdirectory under `'vasm/syntax'`. At least the files `'syntax.h'`, `'syntax.c'` and `'syntax_errors.h'` must be written.

22.4.1 The file `'syntax.h'`

```
#define ISIDSTART(x)/ISIDCHAR(x)
```

These macros should return non-zero if and only if the argument is a valid character to start an identifier or a valid character inside an identifier, respectively. `ISIDCHAR` must be a superset of `ISIDSTART`.

```
#define CHKIDEND(s,e) chkidend((s),(e))
```

Defines an optional function to be called at the end of the identifier recognition process. It allows you to adjust the length of the identifier by returning a modified `e`. Default is to return `e`. The function is defined as `char *chkidend(char *startpos, char *endpos)`.

```
#define NARGSYM "NARG"
```

Defines the name of an optional symbol which contains the number of arguments in a macro.

```
#define CARGSYM "CARG"
```

Defines the name of an optional symbol which can be used to select a specific macro argument with `\.`, `\+` and `\-`.

```
#define REPTNSYM "REPTN"
```

Defines the name of an optional symbol containing the counter of the current repeat iteration.

```
#define EXPSKIP() s=exp_skip(s)
```

Defines an optional replacement for `skip()` to be used in `expr.c`, to skip blanks in an expression. Useful to forbid blanks in an expression and to ignore the rest of the line (e.g. to treat the rest as comment). The function is defined as `char *exp_skip(char *stream)`.

```
#define IGNORE_FIRST_EXTRA_OP 1
```

Should be defined when the syntax module wants to ignore the operand field on instructions without an operand. Useful, when everything following an operand should be regarded as comment, without a comment character.

22.4.2 The file ‘syntax.c’

A syntax module has to provide the following elements (all other functions should be **static** to prevent name clashes):

```
char *syntax_copyright;
```

A string that will be emitted as part of the copyright message.

```
hashtable *dirhash;
```

A pointer to the hash table with all directives.

```
char commentchar;
```

A character used to introduce a comment until the end of the line.

```
char *defsectname;
```

Name of a default section which vasm creates when a label or code occurs in the source, but the programmer forgot to specify a section. Assigning NULL means that there is no default and vasm will show an error in this case.

```
char *defsecttype;
```

Type of the default section (see above). May be NULL.

```
int init_syntax();
```

Will be called during startup, after argument parsing. Must return zero if initializations failed, non-zero otherwise.

```
int syntax_args(char *);
```

This function will be called with the command line arguments (unless they were already recognized by other modules). If an argument was recognized, return non-zero.

```
char *skip(char *);
```

A function to skip whitespace etc.

```
char *skip_operand(char *);
```

A function to skip an instruction's operand. Will terminate at end of line or the next comma, returning a pointer to the rest of the line behind the comma.

```
void eol(char *);
```

This function should check that the argument points to the end of a line (only comments or whitespace following). If not, an error or warning message should be omitted.

```
char *const_prefix(char *,int *);
```

Check if the first argument points to the start of a constant. If yes return a pointer to the real start of the number (i.e. skip a prefix that may indicate the base) and write the base of the number through the pointer passed as second argument. Return zero if it does not point to a number.

```
char *const_suffix(char *,char *);
```

First argument points to the start of the constant (including prefix) and the second argument to first character after the constant (excluding suffix). Checks for a constant-suffix and skips it. Return pointer to the first character after that constant. Example: constants with a 'h' suffix to indicate a hexadecimal base.

```
void parse(void);
```

This is the main parsing function. It has to read lines via the `read_next_line()` function, parse them and create sections, atoms and symbols. Pseudo directives are usually handled by the syntax module. Instructions can be parsed by the cpu module using `parse_instruction()`.

```
char *get_local_label(char **);
```

Gets a pointer to the current source pointer. Has to check if a valid local label is found at this point. If yes return a pointer to the vasm-internal symbol name representing the local label and update the current source pointer to point behind the label.

Have a look at the support functions provided by the frontend to help.

22.5 CPU modules

A new cpu module must have its own subdirectory under 'vasm/cpus'. At least the files 'cpu.h', 'cpu.c' and 'cpu_errors.h' must be written.

22.5.1 The file 'cpu.h'

A cpu module has to provide the following elements (all other functions should be `static` to prevent name clashes) in `cpu.h`:

```
#define MAX_OPERANDS 3
```

Maximum number of operands of one instruction.

```
#define MAX_QUALIFIERS 0
```

Maximum number of mnemonic-qualifiers per mnemonic.

```
typedef int32_t taddr;
```

Data type to represent a target-address. Preferably use the ones from 'stdint.h'.

```
typedef uint32_t utaddr;
```

Unsigned data type to represent a target-address.

```
#define LITTLEENDIAN 1
```

```
#define BIGENDIAN 0
```

Define these according to the target endianness. For CPUs which support big- and little-endian, you may assign a global variable here. So be aware of it, and never use `#if BIGENDIAN`, but always `if(BIGENDIAN)` in your code.

```
#define VASM_CPU_<cpu> 1
```

Insert the cpu specifier.

```
#define INST_ALIGN 2
```

Minimum instruction alignment.

```
#define DATA_ALIGN(n) ...
    Default alignment for n-bit data. Can also be a function.

#define DATA_OPERAND(n) ...
    Operand class for n-bit data definitions. Can also be a function. Negative
    values denote a floating point data definition of -n bits.
```

```
typedef ... operand;
    Structure to store an operand.
```

```
typedef ... mnemonic_extension;
    Mnemonic extension.
```

Optional features, which can be enabled by defining the following macros:

```
#define HAVE_INSTRUCTION_EXTENSION 1
    If cpu-specific data should be added to all instruction atoms.
```

```
typedef ... instruction_ext;
    Type for the above extension.
```

```
#define NEED_CLEARED_OPERANDS 1
    Backend requires a zeroed operand structure when calling parse_operand()
    for the first time. Defaults to undefined.
```

```
START_PARENTH(x)
    Valid opening parenthesis for instruction operands. Defaults to '('.
```

```
END_PARENTH(x)
    Valid closing parenthesis for instruction operands. Defaults to ')'
```

```
#define MNEMONIC_VALID(i)
    An optional function with the arguments (int idx). Returns true when the
    mnemonic with index idx is valid for the current state of the backend (e.g. it
    is available for the selected cpu architecture).
```

```
#define OPERAND_OPTIONAL(p,t)
    When defined, this is a function with the arguments (operand *op,int type),
    which returns true when the given operand type (type) is optional. The func-
    tion is only called for missing operands and should also initialize op with default
    values (e.g. 0).
```

Implementing additional target-specific unary operations is done by defining the following optional macros:

```
#define EXT_UNARY_NAME(s)
    Should return True when the string in s points to an operation name we want
    to handle.
```

```
#define EXT_UNARY_TYPE(s)
    Returns the operation type code for the string in s. Note that the last valid
    standard operation is defined as LAST_EXP_TYPE, so the target-specific types
    will start with LAST_EXP_TYPE+1.
```

```
#define EXT_UNARY_EVAL(t,v,r,c)
    Defines a function with the arguments (int t, taddr v, taddr *r, int c) to
    handle the operation type t returning an int to indicate whether this type has
    been handled or not. Your operation will be applied on the value v and the
    result is stored in *r. The flag c is passed as 1 when the value is constant (no
    relocatable addresses involved).
```

```
#define EXT_FIND_BASE(b,e,s,p)
    Defines a function with the arguments (symbol **b, expr *e, section *s,
    taddr p) to save a pointer to the base symbol of expression e into the symbol
    pointer, pointed to by b. The type of this base is given by an int return code.
    Further on, e->type has to be checked to be one of the operations to handle.
    The section pointer s and the current pc p are needed to call the standard
    find_base() function.
```

22.5.2 The file ‘cpu.c’

A cpu module has to provide the following elements (all other functions and data should be `static` to prevent name clashes) in `cpu.c`:

```
int bitsperbyte;
    The number of bits per byte of the target cpu.
```

```
int bytespertaddr;
    The number of bytes per taddr.
```

```
char *cpu_copyright;
    A string that will be emitted as part of the copyright message.
```

```
char *cpuname;
    A string describing the target cpu.
```

```
int init_cpu();
    Will be called during startup, after argument parsing. Must return zero if
    initializations failed, non-zero otherwise.
```

```
int cpu_args(char *);
    This function will be called with the command line arguments (unless they were
    already recognized by other modules). If an argument was recognized, return
    non-zero.
```

```
char *parse_cpu_special(char *);
    This function will be called with a source line as argument and allows the cpu
    module to handle cpu-specific directives etc. Functions like eol() and skip()
    should be used by the syntax module to keep the syntax consistent.
```

```
operand *new_operand();
    Allocate and initialize a new operand structure.
```

```
void free_operand(operand *);
    Free an operand.
```

```
int parse_operand(char *text, int len, operand *out, int requires);
    Parses the source at text with length len to fill the target specific operand
    structure pointed to by out. Returns PO_MATCH when the operand matches
```

the operand-type passed in `requires` and `PO_NOMATCH` otherwise. When the source is definitely identified as garbage, the function may return `PO_CORRUPT` to tell the assembler that it is useless to try matching against any other operand types. Another special case is `PO_SKIP`, which is also a match, but skips the next operand from the mnemonic table (because it was already handled together with the current operand).

`mnemonic mnemonics[];`

The mnemonic table keeps a list of mnemonic names and operand types the assembler will match against using `parse_operand()`. It may also include a target specific `mnemonic_extension`.

`taddr instruction_size(instruction *ip, section *sec, taddr pc);`

Returns the size of the instruction `ip` in bytes, which must be identical to the number of bytes written by `eval_instruction()` (see below).

`dblock *eval_instruction(instruction *ip, section *sec, taddr pc);`

Converts the instruction `ip` into a DATA atom, including relocations, if necessary.

`dblock *eval_data(operand *op, taddr bitsize, section *sec, taddr pc);`

Converts a data operand into a DATA atom, including relocations.

`void init_instruction_ext(instruction_ext *);`

(If `HAVE_INSTRUCTION_EXTENSION` is set.) Initialize an instruction extension.

`char *parse_instruction(char *,int *,char **,int *,int *);`

(If `MAX_QUALIFIERS` is greater than 0.) Parses instruction and saves extension locations.

`int set_default_qualifiers(char **,int *);`

(If `MAX_QUALIFIERS` is greater than 0.) Saves pointers and lengths of default qualifiers for the selected CPU and returns the number of default qualifiers. Example: for a M680x0 CPU this would be a single qualifier, called "w". Used by `execute_macro()`.

`cpu_opts_init(section *);`

(If `HAVE_CPU_OPTS` is set.) Gives the cpu module the chance to write out OPTS atoms with initial settings before the first atom is generated.

`cpu_opts(void *);`

(If `HAVE_CPU_OPTS` is set.) Apply option modifications from an OPTS atom. For example: change cpu type or optimization flags.

`print_cpu_opts(FILE *,void *);`

(If `HAVE_CPU_OPTS` is set.) Called from `print_atom()` to print an OPTS atom's contents.

22.6 Output modules

Output modules can be chosen at runtime rather than compile time. Therefore, several output modules are linked into one vasm executable and their structure differs somewhat from syntax and cpu modules.

Usually, an output module for some object format `fmt` should be contained in a file `'output_<fmt>.c'` (it may use/include other files if necessary). To automatically include this format in the build process, the `'make.rules'` has to be extended. The module should be added to the `OBJS` variable at the start of `'make.rules'`. Also, a dependency line should be added (see the existing output modules).

An output module must only export a single function which will return pointers to necessary data/functions. This function should have the following prototype:

```
int init_output_<fmt>(
    char **copyright,
    void (**write_object)(FILE *,section *,symbol *),
    int (**output_args)(char *)
);
```

In case of an error, zero must be returned. Otherwise, It should perform all necessary initializations, return non-zero and return the following output parameters via the pointers passed as arguments:

copyright

A pointer to the copyright string.

write_object

A pointer to a function emitting the output. It will be called after the assembler has completed and will receive pointers to the output file, to the first section of the section list and to the first symbol in the symbol list. See the section on general data structures for further details.

output_args

A pointer to a function checking arguments. It will be called with all command line arguments (unless already handled by other modules). If the output module recognizes an appropriate option, it has to handle it and return non-zero. If it is not an option relevant to this output module, zero must be returned.

At last, a call to the `output_init_<fmt>` has to be added in the `init_output()` function in `'vasm.c'` (should be self-explanatory).

Some remarks:

- Some output modules can not handle all supported CPUs. Nevertheless, they have to be written in a way that they can be compiled. If code references CPU-specifics, they have to be enclosed in `#ifdef VASM_CPU_MYCPU ... #endif` or similar.

Also, if the selected CPU is not supported, the init function should fail.

- Error/warning messages can be emitted with the `output_error` function. As all output modules are linked together, they have a common list of error messages in the file `'output_errors.h'`. If a new message is needed, this file has to be extended (see the section on general data structures for details).
- `vasm` has a mechanism to specify rather complex relocations in a standard way (see the section on general data structures). They can be extended with CPU specific relocations, but usually CPU modules will try to create standard relocations (sometimes several standard relocations can be used to implement a CPU specific relocation). An output module should try to find appropriate relocations supported by the object format. The goal is to avoid special CPU specific relocations as much as possible.
